16 **Transformations towards sustainability are more likely when efforts are directed at the following key leverage points, where efforts yield exceptionally large effects (Figure SPM.9): (1) visions of a good life; (2) total consumption and waste; (3) values and action; (4) inequalities; (5) justice and inclusion in conservation; (6) externalities and telecouplings; (7) technology, innovation and investment; and (8) education and knowledge generation and sharing.** Specifically, the following changes are mutually reinforcing: (1) enabling visions of a good quality of life that do not entail ever-increasing material consumption; (2) lowering total consumption and waste, including by addressing both population growth and per capita consumption differently in different contexts; (3) unleashing existing widely held values of responsibility to effect new social norms for sustainability, especially by extending notions of responsibility to include impacts associated with consumption; (4) addressing inequalities, especially regarding income and gender, which undermine capacity for sustainability; (5) ensuring inclusive decision-making, fair and equitable sharing of benefits arising from the use of and adherence to human rights in conservation decisions; (6) accounting for nature deterioration from local economic activities and socioeconomic-environmental interactions over distances (telecouplings), including, for example, international trade; (7) ensuring environmentally friendly technological and social innovation, taking into account potential rebound effects and investment regimes; and (8) promoting education, knowledge generation and maintenance of different knowledge systems, including the sciences and indigenous and local knowledge regarding nature, conservation and its sustainable use.

17 **The eighth point of intervention is promoting education, knowledge generation and maintenance of different knowledge systems, including the sciences and indigenous and local knowledge regarding nature, conservation and its sustainable use. These elements**

are especially important in the face of demographic processes increasing the 'distance' between urbanizing populations and nature. Education generally only fosters changes in consumption, attitudes and relational values conducive to sustainability when it builds on existing understandings, enhances social learning, and embraces a "whole person" approach (*well established)* {5.4.1.8}. Whereas Indigenous Peoples and Local Communities have or had various traditional practices and/or norms that enabled sustainable use of local resources, communities worldwide are facing loss of knowledge transmission along with changes in values and lifestyles. Achieving sustainability from local to global levels will benefit from multiple strategies for education and learning, from recognizing and promoting local environmental knowledge and sustainable practices to integration throughout school curricula (*well established)* {5.4.1.5 and 5.4.1.8}.

18 **Applicable across many intervention points, the first lever is developing incentives and widespread capacity for environmental responsibility. Important actions would often include eliminating perverse subsidies and improving fairness in regulations and incentive programs at every scale (*well established*) {5.4.2.1}.** Whereas many incentive programs are designed in ways that may undermine stewardship and responsibility-taking (*well established)*, there appears to be great scope for subtle changes to policies and programs to instead reinforce commitment with such relational values (*established but incomplete)* {5.4.1.3 and 5.4.2.1}.

19 **Three levers pertain to management and governance institutions. These are reforming business and economic, political and community structures to enable decision-making that (2) promotes integration across sectors and jurisdictions, (3) takes pre-emptive and precautionary actions in regulatory and management institutions and businesses to avoid, mitigate and remedy the deterioration of nature, also monitoring these outcomes, and (4) manage for resilient social and ecological systems in the face of uncertainty and complexity to deliver decisions that are robust in a wide range of scenarios.** Whereas many resources are managed separately with only limited capacity to account for interactions between resources in social-ecological systems, management that integrates more fully across sectors and jurisdictions appears to be central to achieving global sustainability goals (*well established*) {5.4.2.2}. Most resource management and environmental assessment approaches are reactionary, generally enforcing regulations after damage occurs, rather than anticipating it, despite the latter being more suitable for sustainable trajectories (*well established*) {5.4.2.3}. Finally, achieving global goals entails avoiding undesirable collapses of resource systems and restoring underperforming degraded systems, both of which follow from governance for resilience and adaptation (*well established*) {5.4.1.4, 5.4.2.3 and 5.4.2.4}.

20 **The final underlying key intervention that emerges is strengthening environmental laws and policies and their implementation, and the rule of law more generally as a vital prerequisite to reducing biodiversity loss and human and ecosystem health (*well established*). This includes not only strengthening domestic laws but also international environmental laws and policies**, including mechanisms to both harness and rein in the power of business**.** Stronger international laws, constitutions, and domestic environmental law and policy frameworks, as well as improved implementation and enforcement of these rules, are critical in protecting biodiversity and nature's contributions to people (*well established)* {5.4.2.5}.

21 **Although these various changes may seem insurmountable when approached separately, each enabling intervention removes barriers associated with implementing others (*well established*) {5.4.3}. Accordingly and perhaps counter-intuitively, multiple interventions can be achieved more feasibly than individual ones (*well established*) {5.4.3.1}. Governments, businesses, and civil society organizations have many opportunities to boost ongoing processes and to initiate new ones that collectively constitute transformative change (*well established*) {5.4.3.2}.** The most important of these may involve laying the groundwork for changes to leverage points {5.4.1} and levers {5.4.2} at the root of environmental degradation or its reversal, by reducing opposition and obstacles, including those with interests vested in the status quo, but such opposition can be overcome for the broader public good {5.4.3.2}. Chapter 6 further details these challenges and also the opportunities and options for overcoming them, achieving long-term transformational change by initiating short-term measures today.

5.1 INTRODUCTION

While nature and its contributions to people are on a deeply unsustainable trajectory (c.f. chapters 2, 3, and 4), there is a multitude of voices demanding fundamental changes in the global socioeconomic structure and action. To change course toward a sustainable future, numerous organizations and individuals have called for actions at least since the 1980s (e.g., Our Common Future report, Agenda 21, The Future We Want). In response to the calls, many sustainability goals and targets have been set across local to global levels, including Aichi Biodiversity Targets and the 2030 United Nations Sustainable Development Goals (SDGs). Efforts around the world are under way for transformation to sustainability (CBD's Vision for Biodiversity 2050, Bennett *et al.*, 2016). Unlike the Intergovernmental Panel on Climate Change (IPCC), which has clear and single targets and timelines, single targets have limited capacity to address biodiversity declines. While proposals for using a combination of existing metrics exist (e.g., Red List index, Living Planet Index, Biodiversity Intactness Index) (Mace *et al.*, 2018), IPBES' work is guided by these and other existing targets including the Aichi Biodiversity Targets and the SDGs, which represent the closest option for an overall policy target for both ecosystems and human well-being.

In-depth understanding of the past trajectories and the current status of the global coupled human and natural system provides some useful knowledge needed to develop and employ models for a sustainable future (chapter 2; MA, 2005; Pimm *et al.*, 2014). Recent rapid and unprecedented changes, however, mean that historical trajectories may serve us very poorly. Therefore, forward-looking, scenario approaches are required that take those changes into account. Chapter 4 established that most trajectories rooted in current and past trends will fail to meet the full suite of Aichi Targets and biodiversity-relevant SDGs. However, chapter 4 also explored sustainability-oriented scenarios showing that positive futures are possible and failure is not inevitable. This indicates that it may not be too late to meet those goals and targets if bold systemic and incremental changes are made.

Change towards sustainability must be profound, systemic, strategic, and reflexive. Many signs of those changes are already starting to emerge, such as encapsulated in the notion of 'seeds of the good Anthropocene' (i.e., hopeful social-ecological practices ("seeds") that could catalyse and expand (grow) to produce more desirable futures, from addressing situations of social precariousness and vulnerability to recovering habitats for water protection and/or to conserve icons like the giant pandas (Bennett *et al.*, 2016; SFA, 2015; Yang *et al.*, 2017). The key implication of current scenario projections (chapter 4) is that successful change will not happen easily or spontaneously. It will likely require a broad and intense effort, informed by the best available understanding of local to global coupled human and natural systems dynamics. Most of the models and scenarios developed so far (chapter 4) have not been built, intended or applied in ways that address profound and systemic changes.

This finding from chapter 4 has bearing on chapter 5's position on sustainability transitions—as reformist, revolutionary, or reconfigurational (Geels *et al.*, 2015). A reformist position sees sustainability as the outcome of incremental changes and constant improvement of a current system. In contrast, revolutionary positions see sustainability as requiring a radical break with current trajectories. Finally, a reconfigurational position is something in between, involving context-related transformation of everyday practices and their structural embeddings. In this chapter we are philosophically ambivalent about these positions, but the chapter 4 finding suggests that a reformist position is likely to fail to achieve some relevant SDGs or Aichi Targets.

There is no single way to transform towards sustainability, and transformations will play out differently in different places (e.g., Arctic, Antarctic, temperate, tropical regions). The analysis in this chapter highlights possible pathways for transformative change to achieve widely agreed upon sustainability goals. It also identifies key leverage points (where a small change in one factor can generate bigger changes in other factors) (Abson *et al.*, 2017; Meadows, 1999) and 'levers' of change (promising management and governance interventions), without which successful transformation would not be possible. While we use the notion of 'levers' and 'leverage points' metaphorically, recognizing that global systems—as complex social-ecological systems—cannot be manipulated as neatly as can a boulder with a stick, it helps us to clarify our intentions.

What are those pathways, points of intervention and key levers or enabling interventions? In this chapter, we seek to answer this question, both for particular important objectives as well as their connections to other objectives within the larger system. We apply the 'nexus' concept to highlight connections representing stark synergies and trade-offs between different sectors and different goals, such as producing food or mitigating climate or producing energy while conserving biodiversity, resource use options, and ecosystem functioning (Liu *et al.*, 2018).

Two kinds of information are central for this chapter: existing scenarios and broader literatures pertinent to sustainability transformations. First, there are two relevant types of scenarios (target-seeking and policy-screening) that are constructed explicitly to achieve sustainability of Aichi

Targets and biodiversity-relevant SDGs. We interpret target-seeking scenarios as alternative pathways to meet one or multiple specific goals. As there are relatively few examples of such studies, we will also examine sustainability-oriented exploratory scenarios as a proxy. Assessing all these scenarios and pathways helps to explicitly analyse assumptions (e.g., economic, political, demographic, ecological, technological, ideological), pinpoint problems of spatial and temporal scales, and identify some complexities such as nonlinearities and regional differences (IPBES, 2016). Although the analysis is global, it builds on the IPBES regional assessments and meta-analyses of local studies in the literature. Particular emphasis is given to local participatory scenarios (e.g., participatory target-seeking scenarios for social transformation and empowerment) to illustrate and deepen the understanding of how global processes play out on a local scale. This is particularly important for biodiversity assessments, and with the emphasis on indigenous and local knowledge (ILK) and practices we anticipate innovative work on exploring alternative pathways at various scales. A second source of insight is necessary, however, because such scenarios represent only a narrow slice of the literature and a subset of the factors more easily rendered in models (e.g., only partly representing ILK), it is necessary to consult a broad range of literatures on societal and biodiversity change, including a burgeoning literature on pathways and transformative change.

In this chapter, we assess these various sources and distil from them alternative pathways for the transformations needed to achieve biodiversity objectives, the SDGs, to limit global temperature increase to 1.5 degrees Celsius above pre-industrial levels (i.e. The Paris Agreement of the UNFCCC) and to mitigate emerging and existing disaster risks (e.g., the Sendai Framework for Disaster Risk Reduction). We also draw upon policy- and management-screening scenarios, and their potential to simultaneously achieve multiple (sometimes conflicting) goals. This chapter culminates in key lessons for achieving multiple biodiversity and ecosystem service goals in the form of the 'leverage points' and 'levers' that offer unparalleled opportunities for changing unsustainable structures in today's economies and societies.

In the following sections, Section 5.2 provides a conceptual orientation for our approach and explains the methods for our analysis. Section 5.3 summarizes the results of the scenario assessment in the form of a cross-scale analysis of a nexus analysis with six cross-sector foci. Section 5.4 synthesizes insights from the scenario analysis and broader literatures, from which we have identified eight points of intervention ('leverage points') and five key enabling interventions ('levers') for sustainability. Finally, Section 5.5 provides general concluding remarks.

5.2 METHODS OF ASSESSMENT

5.2.1 Conceptual Framework for Assessing Transformation

5.2.1.1 Change towards sustainability requires addressing root causes, implying fundamental changes in society

The society/nature interface can be described in various ways (see for example Descola, 2013; Haraway, 1989; Jetzkowitz, 2019; Latour, 2004; Mol & Spaargaren, 2006; Takeuchi *et al.*, 2016; for further references to ILK-related concepts of the society-nature nexus see chapter 2 and IPBES, 2018). Here we follow IPBES' conceptual framework assuming that institutions, governance systems and other indirect drivers are "the root causes of the direct anthropogenic drivers that affect nature" (Díaz *et al.*, 2015; also see chapter 1). These root causes also affect all other elements of the society/nature interface, including interactions between nature and anthropogenic assets in the co-production of nature's contributions to people (Díaz *et al.*, 2015) In addition to the conceptual framework, we adopt systems thinking because it allows (1) the combination of biophysical and societal understanding of processes, which helps to identify seeds for change, and (2) the combination of results from quantitative and qualitative scenarios and other pertinent literature.

5.2.1.2 Conceptual frameworks addressing transformative change

Various approaches currently discussed in sustainability science address the question of how profound, systemic, and strategic-reflexive changes toward (more) sustainability can be initiated. Our selection of five approaches—complexity theory and the identification of layers of transformation and leverage points, resilience thinking, the multi-level perspective on transformative change, the systems of innovation approach and initiative-based learning—comprises those we identify as widely consistent with the IPBES conceptual framework and mandate. They provide useful concepts for the integration of knowledge on pathways towards a (more) sustainable future and facilitate our imagination throughout the whole chapter.

Complexity theory and leverage points of transformation

Complexity theory attempts to untangle emergent processes in coupled human and natural systems (Liu *et al.*, 2007; Nguyen & Bosch, 2013). It stresses the importance of specific contexts and interdependent influences among various components of systems, which may result in path dependency and multi-causality, where most patterns are products of several processes operating at multiple scales (Levin, 1992). One of the implications of such interdependence is that small actions can lead to big changes (Meadows, 1999), i.e., processes can be nonlinear (Levin, 1998; Levin *et al.*, 2013). These impactful actions are considered *leverage points* because they can produce outcomes that are disproportionate large relative to initial inputs (UNEP, 2012). Although identifying and implementing such leverage points is not easy, the results can be profound and lasting (Meadows, 1999).

Resilience, adaptability and transformability in social-ecological systems

In the context of pathways involving nature and people, changes are bounded not only by technological and social feasibility, but also by spatial and ecological characteristics. *Resilience* thinking enhances our systemic understanding by putting three aspects of social-ecological systems at the center: persistence, adaptability and transformability (Folke, 2016). Resilience refers to the capacity of a system—such as a village, country or ecosystem—to adapt to change, deal with surprise, and retain its basic function and structure (Berkes *et al.*, 1998; Nelson *et al.*, 2007). Adaptability—a component of resilience—represents the capacity to adjust responses to changing external drivers and internal processes, and thereby channel development along a preferred trajectory in what is called a stability domain (Walker *et al.*, 2004). Transformability is the capacity to cross thresholds, enter new development trajectories, abandon unsustainable actions and chart better pathways to established targets (Folke *et al.*, 2010).

A multi-level perspective for transformative change

Complementary to the perspectives above, the *multi-level perspective* sees pathways as an outcome of coupled processes on three levels—niches, regimes and landscapes (Geels, 2002). At the micro level, *niches* are the safe spaces where radical innovations are possible but localized. For innovations to spread to the meso level (*regimes*—interlinked actors and established practices, including skills and corporate cultures), they must overcome incumbent actors who benefit from the status quo. Regimes can either steer for incremental improvement along a trajectory or can affect change in the *landscape* (which includes factors like cultural values, institutional arrangements, social pressures, and broad economic trends). Change at this macro (landscape) level generally involves a cascade of changes, which also affect the regime itself. The multi-level perspective has been particularly useful in understanding socio-technical pathways, which tend to be nested and interdependent across levels. It raises strategic and reflexive questions—for instance, How can we identify actions that yield structural change from individual and local to societal levels, identifying and avoiding blockages and supporting transformations towards sustainability?

System innovations and their dynamics

The *system innovation* (or 'systems of innovation') approach provides a framework for policy interventions to address not only single market failures, but also interconnected challenges through a combination of market mechanisms and policy tools (e.g. OECD, 2015). This approach emphasizes that system innovation generally requires a fundamentally different knowledge base and technical capabilities that either disrupt existing competencies and technologies or complement them. As technology innovation proceeds, it also involves changes in consumer practices and markets, infrastructure, skills, policy and culture (Smits *et al.*, 2010). A key component of innovation for sustainability is thus supportive business models (Abdelkafi & Täuscher, 2016; Bocken *et al.*, 2014; Schaltegger *et al.*, 2012; Seroka-Stolka *et al.*, 2017). Governments also have a role in supporting transitions, however, which extends beyond orchestrating and coordinating policies and requires an active management of transformative change, especially sequencing of policies with the different stages of the transition (Huber, 2008; Mol *et al.*, 2009; Seroka-Stolka *et al.*, 2017).

Learning sustainability through 'real world experiments'

Several strands of research take an approach of so-called *real world experiments* (Gross & Krohn, 2005). These action research approaches emphasize how local and regional initiatives can foster shared values among diverse societal actors (Hajer, 2011), accelerating adoption of pathways to sustainability (Geels *et al.*, 2016). These experimental approaches contribute to niche innovations that are able to challenge existing unsustainable pathways and the regimes that maintain them. Bennett *et al.* (2016) suggest that emphasizing hopeful elements of existing practice offers the opportunity to: (1) understand the values (guiding principles) and features that constitute transformative change (referred to by the authors as the Good Anthropocene), (2) determine the processes that lead to the emergence and growth of initiatives that fundamentally change human-environmental relationships, and (3) generate creative, bottom-up scenarios that feature well-articulated pathways toward a more positive future (see also chapter 2.1). In the multi-scale scenario analysis applied in this chapter, local scenarios may be most closely connected to this approach.

Synthesis

The above conceptual approaches converge on the idea that profound changes in global socioeconomic systems towards sustainability occur as transformation of nested and interlinked structures and processes across various scales. In line with *systems of innovation* approaches, *resilience thinking* and the *multi-level perspective*, we consider profound changes as structural changes. However, these changes do not happen without activating impulses of individuals, groups and organisations. Accordingly, our methods for identifying pathways for sustainable futures includes two key elements: structural analyses of alternative pathways; and cross-cutting analyses of entry points for change ('leverage points') and enabling interventions for transformations ('levers').

5.2.2 Scenarios and Pathways

This chapter mobilises two complementary types of information: scenario and pathway analysis (section 5.3) and knowledge on transformative change (section 5.4). Scenario approaches help open up thinking about the future through qualitative, storytelling approaches and through quantitative systems modelling. These approaches allow for consistent analysis of complex systems and help identify consequences of changes (e.g., technological changes, changing behaviour, alternative management regimes for natural resources). At the same time, classical model-based scenario analyses often oversimplify social realities and have little detail regarding actors, behaviours and policy implementation. Socio-technical and social-ecological pathways analysis gives much more attention to different actors and actions and to finding entry points and levers towards changing pathways. Unfortunately, these approaches often lack a forward-looking perspective (they are generally retrospective) (Turnheim *et al.*, 2015). However, taken together with cross-cutting literatures on transformative change, they can bring a much needed multi-disciplinary perspective to identify and govern pathways for transformative change.

The terms **scenarios** and **pathways** are often used interchangeably especially by the global climate and integrated assessment modeling communities (Rosenbloom, 2017; Turnheim *et al.*, 2015). Here we distinguish the two concepts. **Scenarios** are plausible stories about how the future may unfold that can be told in words, numbers, illustrations, and/or maps—often combining quantitative and qualitative elements. Scenarios are not predictions about the future; rather they are possibilities used in situations of large uncertainty, based on specified, internally consistent sets of underlying assumptions (IPBES, 2016; Raskin, 2005). The global modelling community sometimes uses the term **pathway** to describe the *clear temporal evolution of specific scenario aspects or goal-oriented scenarios* (see **Boxes 5.1-3**). The concept of **pathways** in our chapter includes—but is not limited to—this meaning. More broadly, we consider pathways as "*alternative trajectories of intervention and change, supported by narratives, entwined with politics and power*" (Leach *et al.*, 2010). Scenario exercises may represent selected pathways and their underlying narratives.

5.2.2.1 Pathways for transformative change

The concept of pathways has become increasingly popular to analyse how specific sustainability objectives can be achieved. Pathway approaches attempt to manage complexity—in a bounded, exploratory way—and illuminate new ways of achieving specific societal goals (Geels & Schot, 2007; Turnheim *et al.*, 2015). A rich set of literatures on pathways towards sustainability examines how sustainability might be achieved through different trajectories, often addressing the politics of change and seeking profound changes in global socioeconomic structures (Edenhofer & Kowarsch, 2015; Geels & Schot, 2007; Grin *et al.*, 2010; Leach, 2008; Leach *et al.*, 2018; Loorbach *et al.*, 2017; Luederitz *et al.*, 2017; Olsson *et al.*, 2014; Raskin, 2008; Rosenbloom, 2017; Scoones *et al.*, 2015; Sharpe *et al.*, 2016; Swilling & Annecke, 2012). Few analyses straddle the breadth of perspectives considered here (Loorbach *et al.*, 2017; Turnheim *et al.*, 2015).

Pathways are mostly neither deterministic nor linear, but always context-dependent and evolutionary with emergent properties (the future being shaped by the past). Different pathways achieving the same goals will have different socioeconomic and environmental implications (e.g., effects on nature and its contributions to people). These include 'distributional impacts' that raise justice issues in a given system, and in connected systems through telecouplings (i.e., socioeconomic and environmental interactions over distances). Pathways may also be characterised in other ways: speed (time to reach the goals and targets), depth (degree of differences between starting points, current development trajectories and the goals and targets to be achieved), and scope (dimensions that change to achieve the goals and targets) (Turnheim *et al.*, 2015). As one insight that emerges, pathways of fundamental reconfiguration (or system transformation) often go through distinctive phases of destabilisation → disruption → breakdown of internal structures of the old system followed by an emergence and acceleration of novel features (Loorbach *et al.*, 2017).

In this chapter, pathways refer explicitly to trajectories toward the achievement of goals and targets for biodiversity conservation and management of nature and the full array of the SDGs. Because of the transformative change required, our analysis considers the departure from existing development pathways and vested interests/structures, to make space for new and more sustainable pathways

(Loorbach *et al.*, 2017; Sharpe *et al.*, 2016). Part of this departure may occur by deepening and accelerating existing processes of change.

There are several reasons to identify and analyse alternative pathways. First, no method can identify the best feasible pathway *a priori* due to the many uncertainties, complexities, and societal perspectives in coupled human and natural systems. There is a danger of bias in selecting pathways because the "definition of the alternatives is the supreme instrument of power" (Schattschneider, 1960, p. 66). Second, presenting alternative pathways and their uncertainties may allow for constructive public discourse. It is important to think about how pathways are framed as this shapes how they are understood and addressed, structuring the possibilities and privileging certain responses (Rosenbloom, 2017). Third, presenting alternative policy pathways and their trade-offs and consequences may help avoid the misuse of expertise in policy. With several pathways, policymakers cannot legitimize policy pathways by referring to an alleged "inherent necessity" of a certain policy pathway based on an apparent scientific consensus. To avoid severe bias in the assessment, pathways thus ought to reflect several politically important and disputed objectives, ethical values and alternative policy narratives.

5.2.2.2 Scenario studies

This chapter **combines multiple scenario studies** (through an analysis of their key premises, underlying narratives and results) **and other sources to inform our understanding about possible pathways to the SDGs**, as follows:

- **Types of scenarios considered:** Following the typology of the IPBES methodological assessment report on scenarios and models of biodiversity and ecosystem servicse (IPBES, 2016), our main focus in this chapter are **target-seeking scenarios**, also known as normative scenarios. Such scenarios are built by first defining a future target and then how to get from the present to this future, through quantitative and/or qualitative backcasting (Vergragt & Quist, 2011) or scenario-discovery techniques (Gao & Bryan, 2017), for instance. Since there are relatively few target-seeking scenarios, we also included **sustainability-oriented exploratory scenarios** and **policy-screening scenarios**. The sustainability-oriented exploratory scenarios were those scenarios of evolving key drivers, based on sustainability-oriented archetypes or storylines (Hunt *et al.*, 2012; IPBES, 2016; van Vuuren *et al.*, 2012). In policy-screening scenarios (also known as *ex-ante* scenarios), we analysed specific policy options implications in relation to a reference/*status quo* scenario.

- **Spatial scales:** To extract the key elements that constitute the pathways from scenarios, we employed a cross-scale analysis. While global scenarios indicate broad pathway alternatives, scenarios at finer spatial scales provide more detail and insights in the context of local or regional conditions. We therefore enriched our analysis by bringing elements from finer scales to the pathways discussion. Global scenarios alone may not capture the difficulties of implementing certain measures at local to regional scales, or the unwanted consequences of doing so.

- **Nexus-thinking approach:** Given the inherent complexity of analyzing possible achievement of multiple SDGs, we organized our literature search and analysis using a nexus approach to explore complementary and interconnected perspectives related to terrestrial, marine and freshwater social-ecological systems.

5.2.3 Nexus Thinking, Methods of Analysis

5.2.3.1 Nexus thinking to structure the analysis

Achieving goals and targets related to nature and nature's contributions to people requires holistic approaches to integrate multiple disciplines, across space, over time, and among organizational scales. The need for integration in solving complex problems has long been recognized, leading to a variety of approaches and areas of study. In this chapter, we use a systems approach and nexus thinking to identify synergies and trade-offs when discussing pathways for achieving the SDGs—incorporating thinking across scales, domains, sectors and disciplines (Liu *et al.*, 2015b).

The word nexus (derived from the latin "*nectare*", "to bind or tie"), has long been used in multiple fields to refer to approaches that address linkages between multiple distinct entities (Liu *et al.*, 2018). In recent decades, it became increasingly popular as applied to the study of connections among water, energy and food (the WEF or FEW nexus), usually in the context of climate change, and sometimes with the addition of other issues, such as biodiversity protection and human health (Albrecht *et al.*, 2018; Hoff, 2011). We find nexus thinking a valuable approach *to avoid the natural tendency to retreat into intellectual, sectoral, and institutional silos*. This holistic approach is imperative in the context of the SDGs, given that many of the targets are interconnected (Nilsson *et al.*, 2016) and such interactions can be synergistic and/or antagonistic, involving context-dependent trade-offs (Weitz *et al.*, 2018).

For the above reasons, we use nexus thinking to frame the problem of reaching multiple SDGs together. To keep our analysis manageable and understandable in the complex context wherein everything is connected, we structure our analysis around complementary perspectives, in a multilayered approach. Each perspective can be understood as a *focus* (or lens) to view in detail particular links between terrestrial, marine and freshwater social-ecological systems without disregarding linkages to other aspects **(Figure 5.2)**.

The following six foci reflect core challenges related to conserving nature and nature's contributions to people (the mandate of the global assessment) while achieving the SDGs, given both trade-offs and synergies:

1. *Feeding humanity while enhancing the conservation and sustainable use of nature;*
2. *Meeting climate goals without incurring massive land-use change and biodiversity loss;*
3. *Conserving and restoring nature on land while contributing positively to human well-being;*
4. *Maintaining freshwater for nature and humanity;*
5. *Balancing food provision from oceans and coasts with biodiversity protection; and*
6. *Resourcing growing cities while maintaining the ecosystems and biodiversity that underpin them.*

Our analysis respects the "interconnected and indivisible nature" of the 17 goals (UN, 2015). These six foci relate to all SDGs in some way, although they are oriented around some more strongly than others. Some SDGs are easily related to several of these foci (SDG 2 – Zero hunger, for instance), but human well-being, basic needs, human rights and nature protection underlie all the lenses, including attention to their implications for Indigenous Peoples and

THE NEXUS IN THE LANDSCAPE

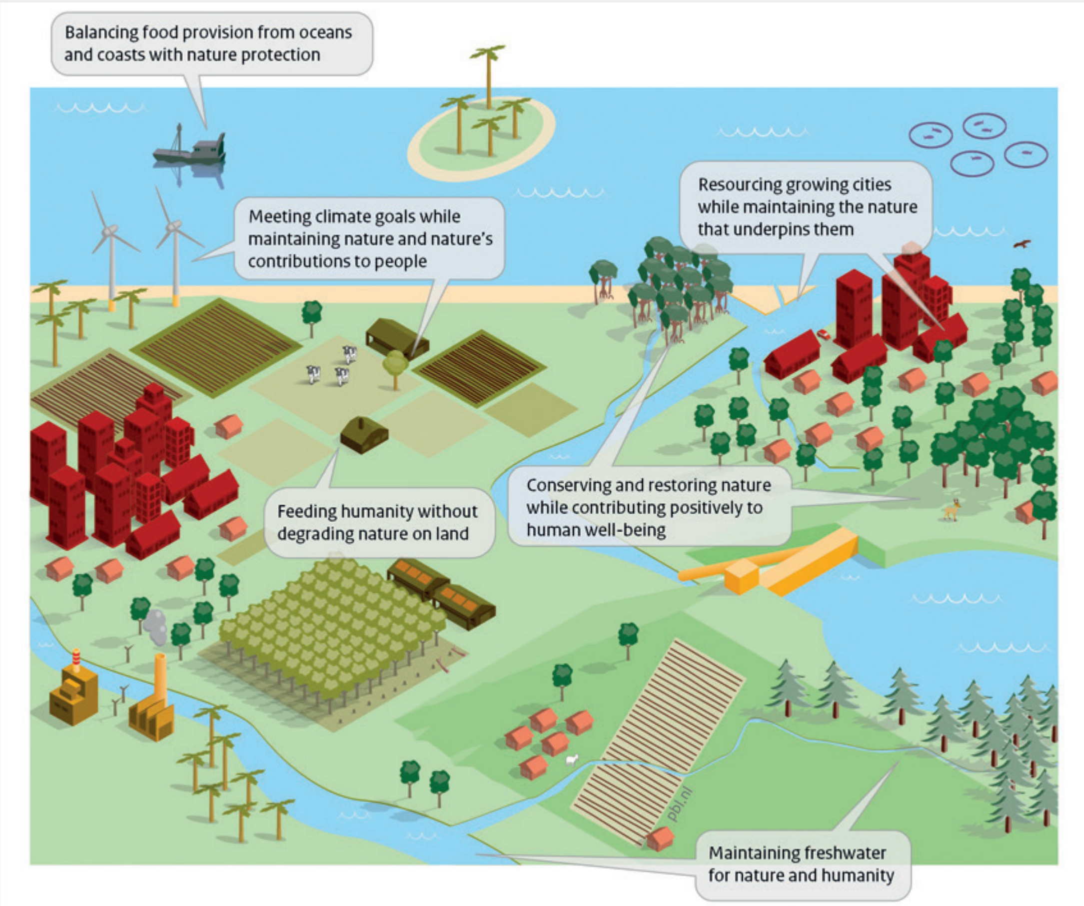

Figure 5 2 **The six interconnected foci of our nexus analysis.**

These complementary perspectives roughly followed divisions in the underlying scenario and pathways literatures addressing a variety of sustainability goals and targets (especially the UN's Sustainable Development Goals, SDGs, and the CBD's Aichi Targets). Source: PBL for this publication.

Local Communities (IPLCs), as **Figure 5.2** illustrates. The first three foci relate strongly to SDG 15 (Life on Land) and its interactions with other SDGs. The fourth addresses freshwater, connecting SDG 6 (Clean Water and Sanitation) to the first three foci through the WEF nexus. The fifth addresses marine resources, also linked to all other foci through the food system, water cycle, pollution and climate change concerns. Finally, the sixth focus addresses cities and their connection to the terrestrial, freshwater and marine resources previously discussed.

We structure our results in Section 5.3 (Pathways derived from the scenario review process) around these foci. For each subsection in 5.3.2, information is organized as follows:

- **Framing the problem**, a brief review about the current situation of the problem under analysis and major trends.
- **What do scenarios say about pathways to achieve the (relevant) SDGs?** We used the available information in the scenario literature (at multiple scales) to identify the *main measures* (actions, policies, governance premises, necessary changes) *directly or indirectly* (through quantified results or narrative premises, for instance) *underlying different scenarios in order to achieve the SDGs simultaneously*. Non-scenario literature was also used to reinforce or complement our synthesis approach.
- **Synthesis about the pathways**, we close each subsection with a synthesis of the main findings, including a diagram illustrating the pathways.

After the six subsections, we conclude 5.3 with a synthesis highlighting common threads across the six foci. We identify levers and leverage points of transformation with a focus on nature and nature's contributions to people (5.3.3). The section emphasizes core convergences and divergences across the different lenses, the synergies and trade-offs between the SDGs, and also the role nature and nature's benefits to people play in reaching the SDGs.

CROSS-SCALE ANALYSIS OF PATHWAYS TO THE SDGS USING NEXUS-THINKING

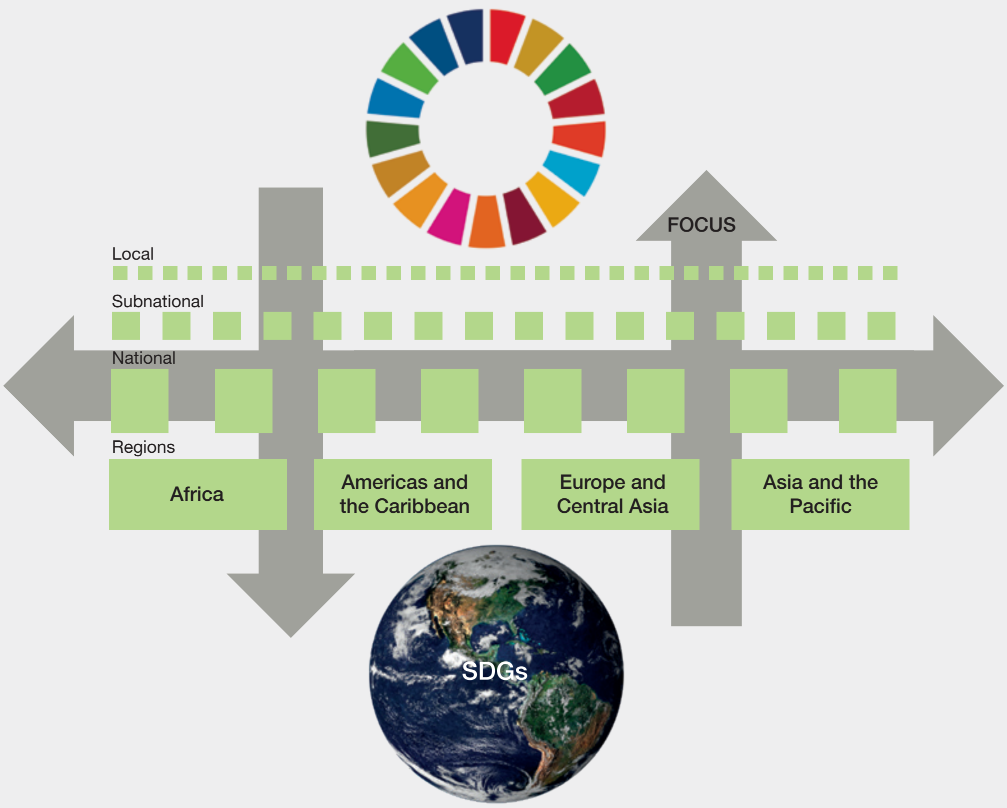

Figure 5 3 **Schematic representation of our multi-scale approach.**

The grey arrows denote the multiple foci we used to structure our analysis. For each focus, we strived to connect information across regions (horizontal arrow) and across spatial scales (vertical arrows).

5.2.3.2 Method for literature search at the global scale

Appendix 5.1 presents the basic search strings we used to select (target-seeking) global scale scenarios. Three alternative strings were used. The first one aimed to encompass all target-seeking scenarios related to nature and nature's contributions to people at the global scale, published after 2006. The second one restricts the search to the selected SDG clusters. The third one expands the selection to some key drivers of change, such as deforestation and restoration processes. To expand the set of studies underlying our analysis, we also investigated global scale exploratory and policy-screening scenario studies, which explicitly followed a sustainability focus in their storylines, with an intent to achieve the SDGs. An example is the new climate scenario SSP1 "sustainable world scenario" of the IPCC (van Vuuren *et al.*, 2017). We recorded key information for each scenario, as the basis for quantitative analysis presented in Section 5.3.1. The literature search for target-seeking scenarios at the global scale yielded 47 studies in total (see Section 5.3.1 and Table SM 5.2 B).

5.2.3.3 Cross-scale analysis

We defined a common process to incorporate information from other scales, to complement global scenarios. The initial source of information about scenarios and pathways at the sub-global scale (regional, national, subnational and local) were the fifth chapters of each of the IPBES regional assessments, which performed broad literature searches on scenarios pertaining their regions. A complementary literature search was conducted for each specific lens/perspective under analysis, similar to the one performed at the global scale. Based on the combined results from all these sources, we tabulated key information about each scenario at different scales (Appendix 5.2). We organized five tables with core information about terrestrial scenario studies (global and the four IPBES regions), and one related to marine scenarios. Each table describes the following: Scale, Region/system, Goal/vision, Type of scenario, Sectors covered, Pathway elements (measures, policies, changes), Scenario 'short name' and Complete reference. We then performed an iterative process to synthesize key information for each scale and region, related to each focus of analysis. Based on this systematization, we distilled key components of pathways projected to achieve the SDGs, which formed the basis for the subsections "What do scenarios say about pathways to achieve the SDGs?", complemented by non-scenario literature and cross-regions linkages. Although we did not adopt a typology of pathways (as in the IPBES European and Central Asia regional assessment), in 5.3 we do indicate alternative—and sometimes contrasting—pathways emerging from the literature. **Figure 5.3** depicts this process.

As mentioned before, this chapter combined methods and procedures to interpret sustainability transitions from different scientific angles. As such, it is an effort towards inter- and transdisciplinary triangulation. Combining the findings from different approaches may enable a more encompassing and more legitimate understanding of the processes, outcomes, and impacts of possible pathways to sustainability. We hope that this will in turn yield more appropriate and legitimate implications for practice and policy (as discussed in 5.4 and chapter 6).

5.3 PATHWAYS DERIVED FROM THE SCENARIOS REVIEW PROCESS

5.3.1 Results of the assessment of global scenarios

5.3.1.1 Overview

The literature search on target-seeking and policy-screening scenarios yielded 47 scenario studies with global coverage. Qualitative, storytelling ("narrative") scenarios were assessed for additional information to determine if, when and why SDGs could be achieved **(Figure 5.4 B)**. At the global scale, target-seeking scenario research is much less elaborated than exploratory scenario research (chapter 4). The IPBES methodological assessment on scenarios and models of biodiversity and ecosystem services notes that target-seeking and policy-screening scenarios have been applied to decision-making mostly at regional and local scales (IPBES, 2016), and therefore are not common at the global scale. Backcasting and scenario-discovery approaches were rare at the global scale, likely due to the inherent complexity of the task at that scale.

The scenarios evaluated consisted of target-seeking scenarios (e.g., Leclère *et al.*, 2018; PBL, 2012; van Vuuren *et al.*, 2015; see **Boxes 5.1 and 5.2**, respectively), followed by policy-screening scenario studies (e.g., Visconti *et al.*, 2016), 'sustainability' exploratory scenarios (e.g., Raskin

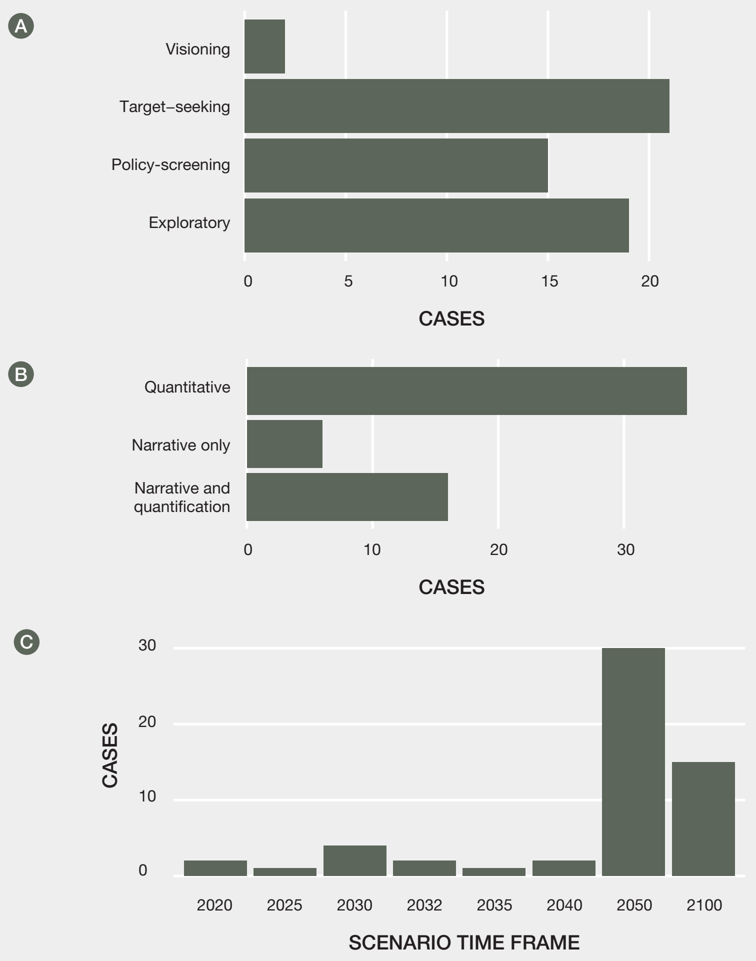

Figure 5 4 **The number of studies from the review on target-seeking scenarios that fulfill the following:**

A target-seeking scenarios, policy-screening scenarios, 'sustainability' scenarios of exploratory exercises, and visioning exercises; B using a quantitative approach, a narrative approach, or both together; and C applying different time frames of analysis (N=34; a given study could score in multiple categories for panel A).

et al., 2002) and a small number of visioning studies (e.g., WBCSD, 2010; see **Figure 5.4 A**). Visioning studies were only taken into account if they went beyond qualitative description of future trajectories for a certain sector and provided quantification and analysis of pathways to realize that vision. The analysis revealed that most selected studies include both narratives (storylines) and quantification of scenarios using models (e.g., UNEP, 2002 Sustainability First Scenario).

In most global scenario studies, biodiversity, ecosystem services (or nature's contributions to people), and implications for human well-being are a few of many aspects being analysed (e.g., PBL, 2012). Regarding temporal scale, long-term projections are most common across the selected studies (present to year 2050, **Figure 5.4 C**). This finding is in line with IPBES (2016), which states that international environmental assessments including scenario exercises typically focus on long timescales. Decision-making, however, often requires both short-term and long-term perspectives (IPBES, 2016), so considering scenarios across different temporal scales is important.

The majority of studies relied on expert knowledge. Only a few incorporated indigenous and local knowledge and perspectives or stakeholder consultations (e.g., Springer & Duchin, 2014). This finding corresponds to IPBES scenarios assessment conclusion that participatory scenario studies predominantly have a local-scale focus, while global scale scenario studies are often developed using expert-based approaches (IPBES, 2016). Participatory scenario methods enhance the relevance and acceptance of scenarios for biodiversity and ecosystem services (IPBES, 2016), and their application could be taken up more often in global-scale scenario exercises.

Sectors most commonly considered

The agricultural sector was the sector most commonly addressed in the scenarios, with 32 of the 47 studies investigating the relationships between agriculture and

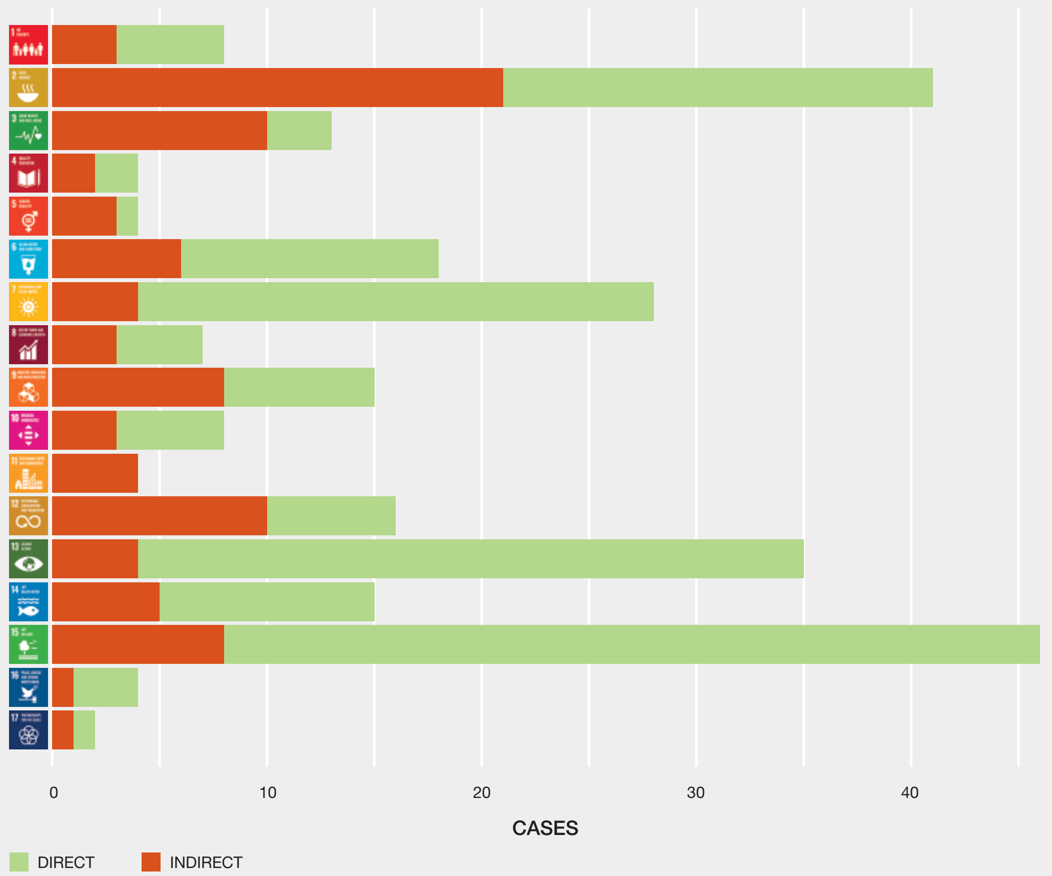

Figure 5 5 **Sustainable Development Goals in Scenarios. Green ("direct") represents scenarios that address an SDG directly; orange represents scenarios that address an SDG only implicitly ("indirect").**

other sectors and factors such as biodiversity, biofuels, deforestation, and climate change (e.g., Eitelberg *et al.*, 2016; Erb *et al.*, 2013; PBL, 2012; Smith *et al.*, 2013; van Vuuren *et al.*, 2015). Concerns ranged from feeding the growing human population to addressing threats from biofuels and managing the availability of land and water (e.g., Flachsbarth *et al.*, 2015; Odegard & van der Voet, 2014; Wirsenius *et al.*, 2010).

The second most prevalent sector was forestry, with 17 studies addressing issues such as land degradation, and competition with agricultural production (e.g., Kraxner *et al.*, 2013; Stavi & Lal, 2015; van Vuuren *et al.*, 2015). In particular, these scenarios addressed issues such as reducing carbon emissions from forest degradation, and competition between forests and biofuel crops (e.g., Smeets *et al.*, 2007; Zarin *et al.*, 2016). Energy and water sectors were considered by 17 and 7 studies respectively. In terms of water, issues addressed include river fragmentation as a threat to river biodiversity, availability of water for agricultural production (particularly emphasizing the threat of agricultural expansion for water resources), and general water efficiency measures needed to reach targets (e.g., Grill *et al.*, 2015; Springer & Duchin, 2014; WBCSD, 2010). The energy sector was addressed largely through efforts to reduce carbon emissions via clean technology, and the competition for land associated with these efforts (Prieler *et al.*, 2013; Rogelj *et al.*, 2018a; van Vuuren *et al.*, 2010, 2017).

SDGs most commonly considered

SDGs pertaining to terrestrial systems were most frequently considered. In particular, SDGs 2 and 15 were commonly investigated, analyzing trade-offs between food security and (terrestrial) biodiversity **(Figure 5.5)**. These studies provide input to investigate the foci on "*Feeding humanity while enhancing the conservation and sustainable use of nature*" Section 5.3.2.1) and "*Conserving and restoring nature on land while contributing positively to human well-being" (*5.3.2.3)*.* Also studied quite frequently were SDGs 6, 7, 12, 13 and 14. The results from the review as well as additional literature thus enables investigating foci related to *Maintaining freshwater for nature and humanity (5.3.2.4)* and *Balancing food provision from oceans and coasts with nature protection (SDG 14, 2, 12; 5.3.2.5)*. Although many studies addressed SDGs 13 and 15, including in concert, additional literature was consulted for the specific lens considering the means of "*Meeting climate goals while maintaining nature and nature's contributions to people***"** (5.3.2.2). Few target-seeking scenarios addressed SDGs 4, 5, 11, 16, and 17. Because of the undisputed relevance of an urbanizing society, however, we investigated the focus "*Resourcing growing cities while maintaining the nature that underpins them*" (5.3.2.6) based largely on secondary literature.

5.3.1.2 Core global studies: integrated pathways to achieve multiple goals

Because detailed examination of particular scenarios and trade-offs is instructive in ways that a general synopsis is not, this section reviews core global studies discussing integrated pathways for achieving multiple goals. Here we pinpoint key characteristics of the pathways discussed in these studies, which feeds into the multi-scale analysis in 5.3.2.

Roads from Rio+20 pathways: this study culminates a series of linked papers and reports (Kok *et al.*, 2018; PBL, 2012, 2014; van Vuuren *et al.*, 2015). It used a backcasting approach to explore the level of effort needed to achieve selected SDGs (accounting for feasibility constraints). **Three alternative pathways were quantified and compared to the 'trend' scenario; each achieved the goals despite variation in management and behaviour change**. The goals align closely with the SDGs (they were based on internationally agreed goals and targets prior to the SDGs) and involve provision of energy and food while mitigating climate change (2 degrees), providing clean air and halting biodiversity loss. The study also examined some related issues including nitrogen, water, and health in the context of population, economic growth, energy and land use. The scenarios were quantified using an integrated assessment model framework IMAGE in combination with related models for biodiversity, human health and climate policy (GLOBIO, GISMO and FAIR, respectively) to provide a global overview while differentiating between world regions (see the IPBES regional assessments for region-specific results). **Box 5.1** synthesizes how the three pathways differ and some key quantitative results in relation to biodiversity.

Alternative pathways to the 1.5 degrees target based on the Shared socioeconomic pathways (SSPs). The SSPs represent five different development trajectories: i.e., sustainable development (SSP1), global fragmentation (SSP3), strong inequality (SSP4), rapid economic growth based on a fossil-fuel intensive energy system (SSP5) and middle of the road developments (SSP2; all are used extensively by the Intergovernmental Panel on Climate Change (IPCC)). Each of the SSPs portrays a storyline quantified using models. These storylines can be combined with different assumptions about climate policy to form a larger context of socioeconomic development and level of climate change (mitigation scenarios, c.f. Riahi *et al.*, 2017; Rogelj *et al.*, 2018b). The sustainable development scenario (SSP1) combined with stringent climate policy is a scenario exploring the route towards a more sustainable world, although the SDGs were not targeted in its development. Mitigation scenarios that achieve the ambitious targets included in the Paris Agreement typically rely on greenhouse gas emission reductions combined with net carbon dioxide removal from the atmosphere, mostly accomplished through

Box 5 1 Roads to Rio+20 Pathways.

Several key **premises** underlie the alternative pathways (Figure Box 5.1.a) and their achievement of sustainability goals (Kok *et al.*, 2018; Table SM 5.3.3):

The **Global Technology pathway** assumes that sustainability objectives are pursued mainly by large-scale application of technological solutions. A high level of international coordination through—for example—trade liberalization and the expansion of global markets drives these responses in all world regions. In terms of land use, sustainable intensification in agriculture may lead to a "land sparing" effect, i.e., efficient use of some lands for production would allow sparing other land from conversion to agriculture and/or dedicate them to conservation (Balmford *et al.*, 2005). The protected area system focuses on continuous natural areas away from existing agricultural land to minimise conflict with agricultural expansion, but large natural areas are not necessarily connected.

The **Decentralized Solution pathway** consists of solutions and technologies that can be implemented on a smaller scale resulting in multi-functional mosaic landscapes and regional diversity, in line with regional priorities. Local and regional markets drive demand. Ecological innovation in mixed land-use systems where natural elements and production landscapes are interwoven may result in a "land sharing" effect (Balmford *et al.*, 2005). Agricultural intensification is achieved by using ecological techniques, such as intercropping, agroforestry, and natural pest control, in combination with natural corridors interwoven with agriculture to enable the extensive use of ecosystem services (Pretty, 2008; Tittonell, 2014). In this pathway, agricultural landscapes comprise at least 30% of natural elements acting as corridors between natural areas, hence reducing fragmentation and providing ecosystem services.

The **Consumption Change pathway** starts from implementing a set of behavioural changes in favour of less resource-intensive consumption. These include ambitious efforts to reduce waste, increase recycling in production chains, reduced energy- and material- intensive lifestyles and a shift towards moderate consumption of meat and dairy, in line with health recommendations. Alongside land "sparing" and "sharing" pathways above, this is the "caring" pathway, reflecting the importance of personal behavioural and consumption choices. This pathway assumes a reduction of 50% in food waste and losses, equalling 15% of the production (IMECHE, 2013). Increases in agricultural productivity are only slightly higher than in the 'trend' scenario. Food consumption change is derived from the Willett diet, characterized by a low meat and egg intake (Stehfest *et al.*, 2009; Willett, 2001).

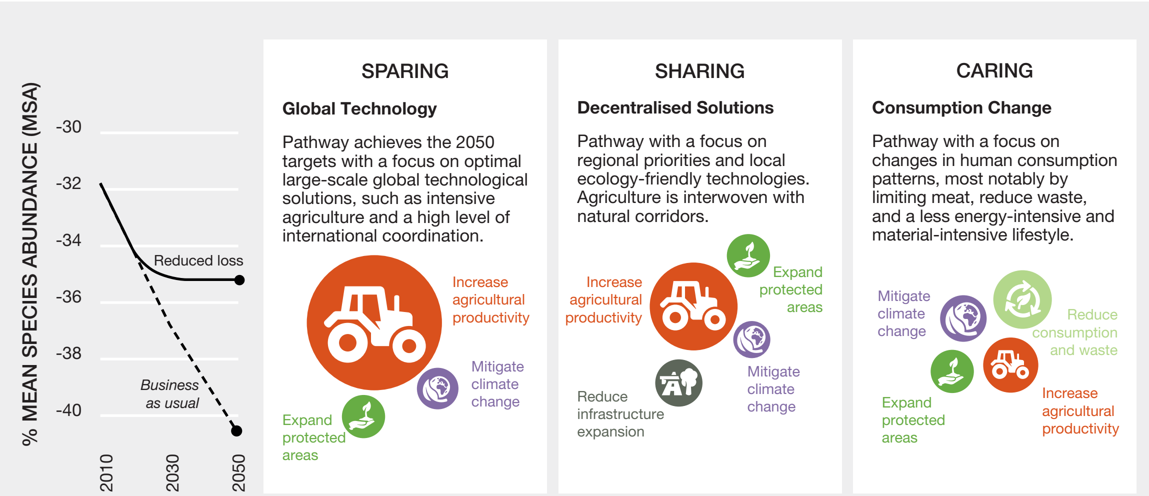

Figure 5 1 A Schematic representation of three alternative pathways to reduce biodiversity loss represented in the Roads to Rio+20 study (see Table SM 5.3.1/5.3.2 for comparison of premises).

Source: PBL (2017).

Results

According to the study, all pathways achieve the assumed 2050 targets (Table SM 5.3.1) and would reduce biodiversity loss in the coming decades (avoided Mean Species Abundance (MSA) loss is 4.4-4.8% MSA, compared to 9.5% MSA loss in the 'trend' scenario **(Figure Box 5.1.b)**. Under the Global Technology pathway the most important contribution by far comes from increasing agricultural productivity on highly productive lands. Under the Consumption Change pathway, significant reduction in consumption of meat and eggs as well as reduced waste means that less agricultural production would be required, thus reducing associated biodiversity loss. Under the Decentralised Solutions pathway, a major contribution comes from avoided fragmentation, more ecological farming and reduced infrastructure expansion. Under all scenarios, climate change mitigation, the expansion of protected areas and the recovery of abandoned lands also significantly contribute to reducing biodiversity loss. Further positive results could be achieved by combining various options from the pathways, especially by increased consumption changes in the other pathways. This would result in reversing trends of biodiversity loss (see **Box 5.3** on Bending the curve).

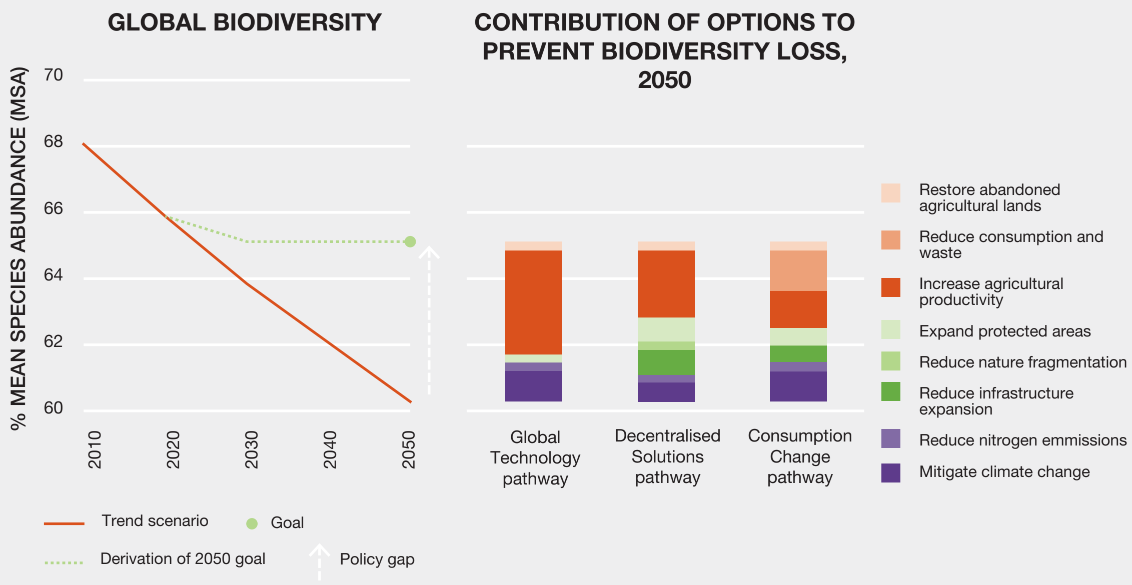

Figure 5 1 B **Measures in the alternative pathways that contribute to biodiversity goals.**

The Rio+20 scenarios have also been used to explore the impact of alternative pathways on extinction risk and abundance of large mammals, revealing that both bottom-up behavioural change (Consumption Change) and top-down technology and policy changes (Global Technology) can reverse global biodiversity decline in the short term, but the onset of delayed climate change impact may require further mitigation strategies.

This study was also one of first to discuss synergies and trade-offs among food, biodiversity, energy, health and climate targets (see Table SM 5.3.3), some of which were explicit in the models. However, some potential trade-offs remain unquantified, such as the use of pesticides and their impacts on health and biodiversity. Source: PBL (2012).

The following publications contain more details (Kok *et al.*, 2018; PBL, 2012, 2014; van Vuuren *et al.*, 2015; Visconti *et al.*, 2016), and there is discussion about their regional results in each IPBES regional assessment.

large-scale application of bioenergy with carbon capture and storage, and afforestation (Doelman *et al.*, 2018; Rogelj *et al.*, 2018a). Using the IMAGE integrated assessment model, van Vuuren *et al.* (2018) explored the impact of **additional measures (beyond SSP mitigation scenarios)** that also include lifestyle change, additional reduction of non-CO_2 greenhouse gases and more rapid electrification of energy demand based on renewable energy (see **Box 5.2** for more detail).

Alternative pathways for bending the biodiversity curve: the 'Bending the Curve' study (Leclère *et al.*, 2018) quantitatively modelled ambitious target-seeking scenarios aiming at reversing biodiversity trends in the 21st century from negative to positive (Mace *et al.*, 2018). This interdisciplinary effort between different modelling communities focuses on biodiversity as affected by human land use and relies on: a) spatially explicit datasets of biodiversity, modelled impacts of land use on biodiversity, and existing scenario frameworks (e.g., SSPs and representative concentration pathways, RCPs); b) integrated assessment models, in particular their spatially explicit land-use modeling components; c) global spatially explicit biodiversity models (also used in chapters 2 and 4) assessing an array of biodiversity impacts from land-use changes. The storylines of existing SSP/RCP scenarios were enriched with more ambitious conservation storylines and quantified via additional datasets generating new scenarios of future trends in land use. These new scenarios considered further actions for biodiversity, such as increased conservation efforts (increased extent and management efficiency of protected areas, increased restoration and landscape-level conservation planning), but

Box 5 2 Alternative pathways to the 1.5 degrees target.

Compared to the default SSP2 1.9 and 2.6 (radiative forcing level of 1.9 and 2.6 W m–2 in 2100, respectively), alternative scenarios to achieve the 1.5 degrees goal are built using the following premises (van Vuuren *et al.*, 2018):

- Rapid application of best available technologies for energy and material efficiency in all relevant sectors in all regions;
- Higher electrification rates in all end-use sectors, in combination with optimistic assumptions about integration of variable renewables and costs of transmission, distribution and storage;
- High agricultural yields and application of intensified animal husbandry globally;
- Implementation of best available technologies for reducing non-CO_2 emissions and full adoption of cultured meat in 2050;
- Consumers change their habits towards a lifestyle that leads to lower GHG emissions (less meat-intensive diet, less CO_2-intensive transport, less intensive use of heating and cooling and reduced use of several domestic appliances);
- Lower population growth (compatible with SSP1);
- The combination of all options described above.

Results

Although the alternative options explored greatly reduce the need to actively remove atmospheric CO_2 to achieve the 1.5 °C goal, nearly all scenarios still rely on bioenergy with carbon capture and storage and/or reforestation (even the hypothetical combination of all alternative options still captured 400 $GtCO_2$ via reforestation). Although not directly estimating impacts on biodiversity targets, these results are important due to the large-scale reforestation process envisioned in the mitigation scenarios. The set of alternative scenarios suggests a diversity of possible transition pathways, including via changing consumption patterns.

The results point out the need for a more diverse portfolio of options than currently discussed in the mitigation scenarios and an open debate concerning their contributions. This could provide more flexibility to ensure that goals are reached. However, it is important to note that the adoption of alternative pathways also might convey substantial regional impacts. To illustrate, **Figure Box 5.2** compares the spatially explicit results of SSP1 and SSP1 1.9, as implemented by the IMAGE model in Doelman *et al.* (2018).

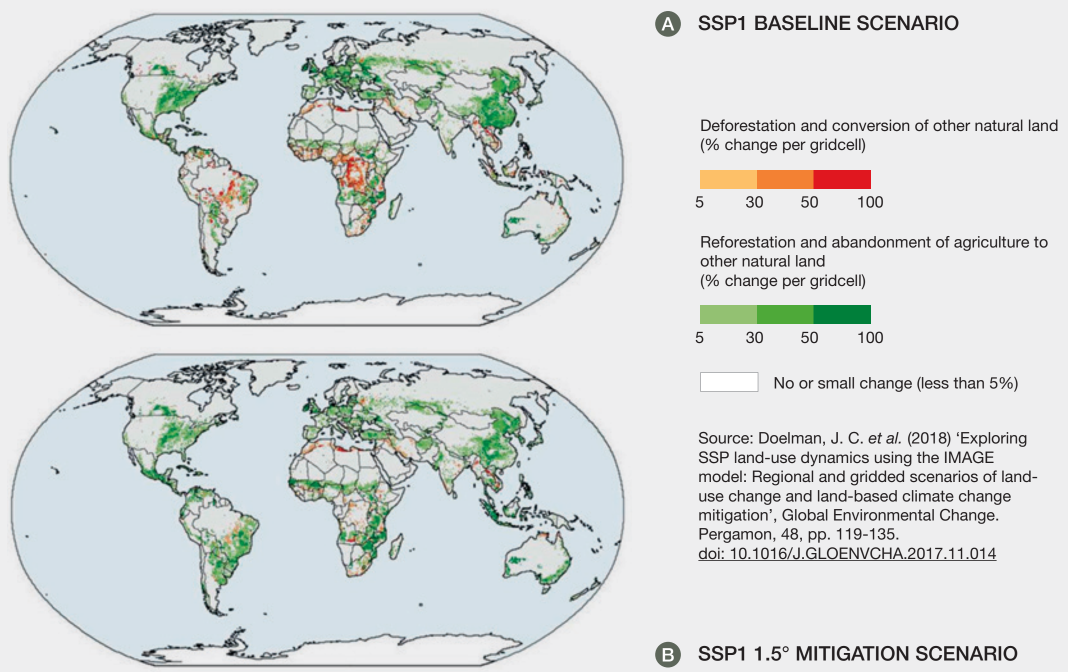

Figure 5 2 **Change in land use (percentages of grid cells) between 2010 and 2100; deforestation and conversion of other natural land to agriculture (red) and reforestation and abandonment of agriculture to other natural land (green) for SSP1 baseline scenario and SSP1 1.5 °C mitigation scenarios (1.9 W/m²).**

Box 5 3 Bending the curve scenarios: towards pathways for ambitious biodiversity targets.

In addition to a baseline (BASE) scenario (based on the "Middle of the Road" SSP2), this study considers six "wedges scenarios" in which various efforts are implemented in order to "bend" the curve of biodiversity loss. The scenarios do not assume strong climate mitigation efforts, nor do they account for future changes in climate or any threat to biodiversity other than habitat loss. The **premises** underlying the six wedge scenarios are as follows:

Increased conservation efforts ("C scenarios"):

a) Increasing protection: any change in land use detrimental to biodiversity (according to PREDICTS' Biodiversity Intactness Index (Hudson *et al.,* 2017)) is ceased from 2020 onwards for all areas identified by the potential protected areas layer (see sections 4.1 and 5.2 in Leclère *et al.*, 2018).

b) Increasing restoration and landscape-level conservation planning: over the entire land area, incentives are gradually put in place to favor land-use changes resulting in biodiversity improvements from 2020 onwards. The net impact on biodiversity (gain or loss) of a particular land-use change is based on PREDICTS' Biodiversity Intactness Index for the two land uses, while the relative importance (for biodiversity) of a given parcel of land derives from the regional restoration priority layer (see sections 4.3 and 5.2 in Leclère *et al.*, 2018).

Demand-side efforts beyond SSP1 ("DS scenarios"):

a) Shifting towards healthier diets: dietary preferences evolve towards 50% less meat compared to the baseline scenario, linearly between 2020 and 2050 (the corresponding animal calories are replaced by plant-based calories) except for regions with low shares of meat in diets like Middle-East, Sub-Saharan Africa, India, Southeast Asia and other Pacific islands (where dietary preferences follow the reference scenarios)..

b) Reducing waste throughout the food supply chain: total waste (losses in harvest, processing, distribution and final household consumption) decreases by 50% by 2050 compared to the baseline, linearly between 2020 and 2050.

Supply-side efforts ("SS scenarios"):

a) Sustainably increasing productivity: crop yields develop following SSP1, assuming in particular a rapid convergence of land productivity in developing countries to that of developed countries.

b) Increasing trade in the agricultural sector: trade of agricultural goods develops according to SSP1, with a more globalized economy and reduced trade barriers.

Combined efforts scenarios: the above efforts are combined by pairing increased conservation and supply-side efforts in the C+DS scenario, increased conservation and supply-side efforts in the C+SS scenario, and all efforts together in the integrated action portfolio (IAP) scenario.

Results show that bending the curve is possible within the 21st century for several feasible driver scenarios. **Figure Box 5.3** shows that combining different action wedges allow biodiversity trends to be reversed before 2050 (IAP scenario), instead of continuing declines for BASE scenario. This predicted reversal of trends is similar across all metrics, indicating that future land-use scenarios can be robustly favorable to biodiversity.

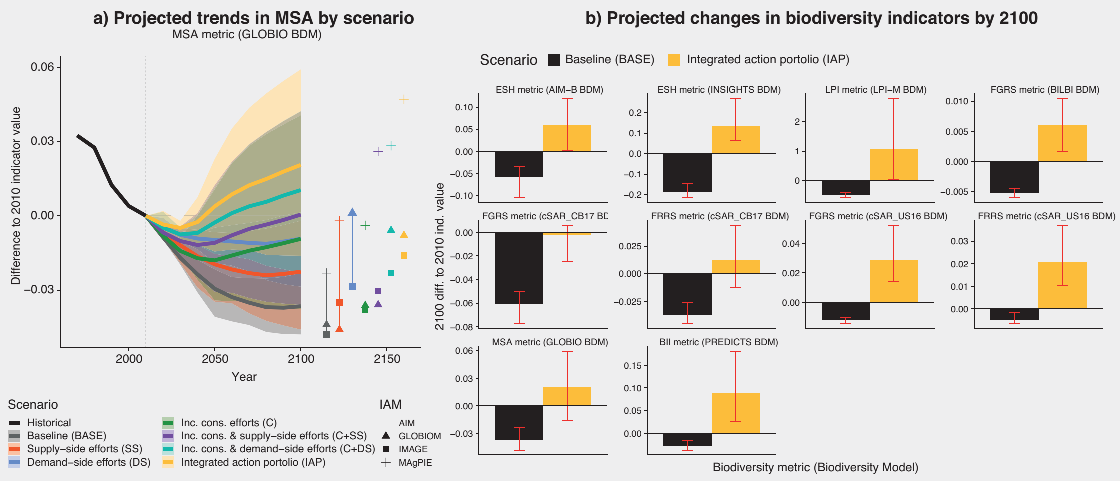

Figure 5 3 **Illustration of results from the Bending the Curve fast-track analysis results.**

The left panel illustrates the estimated change in GLOBIO's Mean Species Abundance index (MSA) from 2010 to 2100 (as compared to 2010) for the land-use component of four integrated assessment models (AIM, GLOBIOM, IMAGE and MAgPIE; the range across IAMs is depicted by ribbons, the average by lines) and 7 scenarios between a business as usual

(BASE) and an Integrated Action Portfolio (IAP) scenario cumulating all efforts to reverse biodiversity trends. The right panel presents the change in various biodiversity indicators estimated by 2100 as compared to 2010 for 2 scenarios (BASE and IAP): BILBI and countryside Species Area Relationship models provide measures of extinctions (the Fraction of Regionally/Globally Remaining Species FRRS & FGRS); GLOBIO and PREDICTS both provide measures of ecosystem integrity through the Mean Species Abundance (MSA) index and the Biodiversity Intactness Index, (BII) respectively; INSIGHTS and AIM-Biodiversity provide a measure of habitat changes through the Extent of Suitable Habitat (ESH) index; and wildlife population density trends are estimated through the Living Planet Index (LPI). The bars indicate the average across IAMs, while red error bars indicate the dispersion across IAMs.

The multi-model assessment framework allows for quantitative assessment of uncertainties associated with land-use projections and their underlying drivers. The contribution of individual drivers and combinations of drivers to stepwise biodiversity improvements has also been quantified. For example, although larger conservation and restoration efforts are key to halting loss and engaging biodiversity onto a recovery path, such a reversing of global biodiversity trends will only be possible by 2050 if our food system achieves a feasible but ambitious transformation.

also demand-side (shift in diets towards less meat, reduced waste) and supply-side efforts (crop yield improvement and reduced trade barriers). Scenarios were fed into the integrated assessment models to generate land-use change projections. Finally, biodiversity models were used to assess whether these spatially explicit land-use change projections over the 21st Century are able to reverse biodiversity trends on a multitude of biodiversity indicators. **Box 5.3** describes measures embedded in the pathways and synthesizes core results.

Two core conclusions can be drawn from the analysis of these studies:

1. **Pathways and narratives:** Different pathways can potentially yield achievement of the same sustainability goals, sometimes with contrasting narratives.**Recognizing the existence of alternative narratives, including their complementarities and tensions, is central to advance the discussion of necessary transformations**, as alternative pathways pose different challenges, trade-offs and synergies among targets (Leach *et al.*, 2010; Luederitz *et al.*, 2017; **Boxes 5.1-3**). For instance, focusing on lifestyle change may greatly decrease the need for future choices related to resource use. Different narratives also uncover power structures and winners and losers of anticipated transformations. Reduced meat production may have implications for economies of producing countries. System lock-ins may be reinforced by certain pathways. Relying only on land-sparing pathways may have positive implications for large-scale industrial agriculture while undermining small-scale farmers. In the following sections, alternative narratives and pathwaysare recognized and highlighted through examples.

2. **SDGs and the Paris Agreement goals:** Scenarios consistent with the Paris goals to reduce GHG emissions include options such as switching to zero- and low-carbon energy options, increasing energy efficiency, using carbon capture and storage (CCS), reducing non-CO_2 GHG emissions, eliminating emissions related to land-use change and stimulating afforestation. Van Vuuren *et al.* (2018), for instance, concluded that GHG targets can be achieved through reduced production of meat and dairy products and intensification of agricultural production, together limiting conversion of unmanaged land. Such a pathway may also promote land-use changes that minimize releases of carbon stored in vegetation and soils, thereby potentially preserving some biodiversity-rich areas. However, mitigation scenarios may also rely on development of short-rotation bioenergy plantations—increasing pressure to convert unmanaged land—and afforestation of non-forested areas for both carbon sequestration and extractive use.

These climate mitigation scenarios suggest four key points: (a) the **biodiversity impacts of afforestation** will depend on where afforestation occurs and how the resulting plantations and forests are managed; (b) such pathways indicate a **land-constrained scenario for food production** due to competition with large-scale reforestation and biofuels; (c) a key underlying premise of the SSPs pertains to population size and ensuing consumption trends. The population dynamics for the different SSPs (Abel *et al.*, 2016) range from a very high global population of almost 13 billion by 2100 down to just 7 billion in SSP1—a shade lower than the current population of 7.6 billion. Therefore, **the feasibility of the options discussed above depends on reduced population growth, and consequently a considerably lighter pressure on resources** (energy, land, water)(see 5.4.1.2). Finally, (d) **such studies assume appropriate, timely and effective governance of such large-scale transformations** in different geographic contexts (see 5.4.2.1-5).

5.3.2 How to achieve multiple SDGs: a cross-scale analysis using nexus thinking

5.3.2.1 Feeding humanity while enhancing the conservation and sustainable use of nature

Framing the problem

Today, agriculture accounts for 38% of Earth's terrestrial surface (Foley *et al.*, 2011) and produces enough calories for all people in the world (Ramankutty *et al.*, 2018). Many millions of people have been lifted out of hunger but food security continues to be a major challenge globally (Godfray *et al.*, 2010). The Food and Agriculture Organization (FAO) reports that the number of undernourished people increased to 821 million in 2017. Similarly, stunting and wasting continue to affect children under the age of five, with more than 150 million and 50 million children affected in the same year, respectively. At the same time, obesity is rising, affecting more than 670 million people worldwide (FAO, 2017).

There are many reasons for the mismatch between the increased availability of food and the continued existence of undernourishment. On the supply side, food production is not evenly distributed globally, and regions differ in terms of yield, irrigation, nutrient application and climate impacts, among other factors (Lobell *et al.*, 2011; Monfreda *et al.*, 2008; Mueller *et al.*, 2012; Ramankutty *et al.*, 2018; Searchinger *et al.*, 2013). Consumption is further impeded in some places by access, affordability, and poverty. Added to this is increasing food waste across the food value chain from production to consumption (Gustavsson *et al.*, 2011; Odegard & van der Voet, 2014; Smith *et al.*, 2013), market influences on food price (Headey & Fan, 2008; O'Hara & Stagl, 2001) and other factors affecting the distribution of food. Besides, in many regions the expansion of industrial agriculture–via incentives from trade agreements, government subsidies, and global mergers of large agribusinesses corporations–threatens small-scale agriculture, still a significant and in many countries the main contributor to food production and food security (IPES-Food, 2016). Beyond agriculture, hunting, gathering, and herding systems continue to be crucial for locally appropriate food security, and such systems have sometimes suffered at the expense of subsidies for and externally imposed notions of appropriate nutrition and food production (Council of Canadian Academies, 2014; EALLU, 2017). Despite their importance, these non-agriculture food systems represent an important gap in literatures on scenarios and pathways (except for fishing, see 5.3.2.5 and also 5.3.2.4); accordingly, our focus in this section is largely on agriculture.

Agriculture is a fundamental driver of global biodiversity loss through its area expansion and the increase of pollutants and of resources used in production (including irrigation water, fertilizers and pesticides) (see chapters 2, 3). Meanwhile, agriculture depends strongly on healthy ecosystems for a diversity of supporting ecosystem processes, including nutrient remineralization, soil health, insect pollination, and biological pest control (Power, 2010; Seppelt *et al.*, 2017). **The core question addressed here is whether and how agriculture and associated food systems will be able to meet the needs of the global population in the coming decades, without further degrading natural resources (and possibly even restoring some).** Addressing this question requires consideration of the globalization of food systems and the varying contributions and roles that different regions play in food production **(Figure 5.6)**.

We organize the discussion about pathways in relation to agricultural production, the supply chain and consumers. While much of the literature has focused on reconciling agricultural production and conservation, other issues also need attention. These include food distribution systems, waste, poverty, inequality and personal food preferences, all of which provide direction for tackling hunger and malnutrition, and ultimately, environmental degradation (Bennett, 2017; Cassidy *et al.*, 2013; Tilman & Clark, 2014). It is also critical to reflect on current trends of global food production systems becoming more capital-intensive. The concentration of food production in fewer hands, and the centralized control of inputs pose a significant threat to small-scale agriculture (FAO, 2017).

What do scenarios say about how to achieve these goals?

Agricultural production pathways

Considerable debate addresses how best to balance food production and nature conservation, minimizing land clearing and biodiversity loss (Balmford *et al.*, 2005; Bruinsma, 2011; Erb *et al.*, 2016; Foley *et al.*, 2011; Kok *et al.*, 2014; Phalan *et al.*, 2011; Smith, 2018; Smith *et al.*, 2013; Tscharntke *et al.*, 2012). Two interconnected aspects are key: (1) where food is produced and nature is conserved (spatial distribution of nature and agricultural lands), and (2) how and by whom food is produced.

Some argue that achieving this balance requires land sparing (intensification of agriculture for high yields and the setting aside areas for conservation—a binary approach), while others argue for land sharing (integrated approaches where these two forms of land-use are blended and wildlife-friendly techniques are applied). Based on different approaches, scholars independently come to the conclusion that agricultural yields can be increased substantially without further expansion of agricultural area (Delzeit *et al.*, 2018; Erb *et al.*, 2016; Mauser *et al.*, 2015) but with intensification of land use. In the extreme, biologist E. O. Wilson has called for protecting “half Earth” (Wilson, 2016), producing more and healthier food through sustainable intensification on existing farmland, and returning the other half of land to nature. Lately, many authors have argued that this simplified dichotomy (“land sparing” vs. “land sharing”) limits future possibilities (Kremen, 2015). A stringent application of one of the two strategies everywhere is undesirable, as what is optimal may strongly differ regionally based on socioeconomic, cultural and ecological characteristics—and the region’s role in global food systems **(Figure 5.6)**.

This leads to another important debate regarding the nature and scale of agricultural systems. Agro-industrial systems, consisting of input-intensive monocultures and industrial-scale feedlots currently dominate farming landscapes (FAO, 2017; IPES-Food, 2016). The uniformity at the heart of these systems, and their reliance on chemical fertilizers, pesticides and preventive use of antibiotics, systematically yields negative outcomes and vulnerabilities, which might lead to system lock-ins (Geiger *et al.*, 2010; Hunke *et al.*, 2015; Wagner *et al.*, 2016). To avoid such problems, there is a need to scale up sustainable practices, including agroecology (FAO, 2017; IPES-Food, 2016; Muller *et al.*, 2017; Rockström *et al.*, 2017). A recent study explored the role that organic agriculture could play in sustainable food systems (Muller *et al.*, 2017). These authors showed that—in combination with reductions of food waste and food-competing feed, with correspondingly reduced production and consumption of animal products—organic agriculture could feed the world using less land than the reference scenario, and that it could also bring several environmental benefits, including a decrease in pesticide use.

Agroecology practices can play a key role. Applied to small-holders they can boost food security; smallholders rather than large-scale farming are the backbone of global food security efforts, given that 80% of the hungry live in developing countries and 50% are smallholders (Tscharntke *et al.*, 2012). The move towards sustainable agriculture may include the adaptation and transfer of agroecological practices and technologies to areas and nations with relatively low yields (‘bridging the yield gap’; Pradhan *et al.*, 2015). Such efforts could enable more efficient nutrient use worldwide, but they are no substitutes for regional strategies to achieve food security. Payment for ecosystem services (PES) programs are frequently mentioned in regional to local scenarios (SM 5.2) as an important complementary measure to help facilitate the transition (e.g., Kisaka & Obi, 2015; see 5.4.2.1 about incentives).

The majority of current integrated global scenarios largely rely on a land sparing/intensification approach (see Section 5.3.1.2, SM 5.2.B), allocating food production across the globe to the most suitable lands, and envisioning extensive land restoration. The Roads to Rio+20 is an exception, also representing a land sparing pathway **(Box 5.1)**. Regional to local scenarios (SM 5.2.C to F) tend to explore multiple pathways, detailing the challenges and opportunities of such pathways, and in some cases contrasting perspectives. Regional to local scenarios highlight the following as core pathway elements to achieve the goals of food production and nature conservation: spatial planning; strengthened protected areas; measures to avoid the social and environment rebounds of agricultural intensification; resolution of land tenure issues; routine law enforcement; participation in strengthened governance structures. The importance of international cooperation and cross-national governance structures has been stressed by several scenario studies given the globalization of production and the need to upscale local innovations (Geels *et al.*, 2016; PBL, 2014; Pouzols *et al.*, 2014; van Vuuren *et al.*, 2015).

Consumer pathways: changes and diets and pressure for certified products

Consumers can influence supply chains and agriculture production through consumption choices, including changes towards healthier and environmentally friendly diets. The heterogeneous trends of population growth and urbanization across different regions, and different countries’ positions as consumers or producers in the globalized food system, underlie such discussions.

At the global scale (Table SM 5.2 B), several authors have discussed the impacts of alternative diets on land-cover change and, consequently, on biodiversity loss (Delzeit *et al.*, 2018; Erb *et al.*, 2016; Popp *et al.*, 2010; Schader *et al.*, 2015; Stehfest *et al.*, 2009). For instance, Stehfest *et al.*’s (2009) four scenarios of dietary variants—all of which reduce meat consumption (ranging from partial to complete elimination of meat from global diets)—lessened projected land-use change (and impacts on ecosystem services more broadly) and emissions. Potential instruments discussed in such studies include regulation, economic incentives, and information campaigns.

Regional to local scenarios focused less on consumption and diet changes, except in the US and EU. In the **United States**, for instance, Peters *et al.* (2016) evaluated ten alternative diet scenarios (varying the content of meat and dairy consumption) based on projected human carrying capacity (persons fed by unit land area). Their results indicate that: (a) diet composition greatly influences overall land footprint, and imply very different allocation of land by crop type; (b) shifts toward plant-based diets may need to be accompanied by changes in agronomic and horticultural research, extension, farm operator knowledge, infrastructure, livestock management, farm and food policy, and international trade; and (c) diets with low to modest amounts of meat outperform a vegan diet, and vegetarian diets including dairy products performed best overall.

In meat producing countries like **Brazil**, recent scenario studies tend to focus on measures to transform cattle ranching (see for example MCTI, 2017; Strassburg *et al.*, 2014; see Table SM 5.2.C). These studies argued that even with current trends in meat consumption, a boost in the current low productivity of the sector—combined with adequate measures to avoid social and environmental rebounds of intensification—could decrease deforestation and even liberate area for restoration. In contrast, global scenarios, particularly recent ones aligned to 1.5°C targets (see **Box 5.2 and 5.3**), tend to consider a reduction in meat consumption as a necessary measure, given competition for land (biofuels and reforestation), emission and pollution concerns.

Finally, consumer pressure for goods produced in an environmentally friendly and socially just manner is a strong mechanism for transforming food systems. Certification programs are often mentioned as an important pathway element in scenarios at all scales (SM 5.2), as further discussed below (and in 5.4.3.2; chapter 6).

Supply chain pathways

Supply chains link producers and consumers via local to global networks of processors, traders, retailers, investors and banks. The relatively small number of actors (compared to producers and consumers) provides opportunities for levers of transformation, as such key actors may influence decisions made by primary producers and others throughout supply chains (Kok *et al.*, 2014). Partnerships between public and private actors involved in supply chains seem promising for mainstreaming biodiversity protection and engaging multiple levers of change.

A good example of supply chain initiatives is the Soy Moratorium in Brazil's Amazon, a production system telecoupled via global markets (see also chapter 6). This Moratorium was the first voluntary zero-deforestation agreement implemented in the tropics and set the stage for supply-chain governance of other commodities, such as beef and palm oil (Gibbs *et al.*, 2015). In response to pressure from retailers and nongovernmental organizations (NGOs), major soybean traders signed the moratorium, agreeing not to purchase soy grown on lands deforested after July 2006 in the Brazilian Amazon. A monitoring system verifies individual producers. Although few integrated quantitative scenarios represented such measures explicitly, qualitative scenarios often mentioned them as key elements, tied to other governmental and civil society measures (for instance, Aguiar *et al.*, 2016).

The trend of concentration of food systems in few companies also tends to create major asymmetries in economic and power relations. Such asymmetries must also be addressed to ensure fairness and underpin necessary changes regarding food waste, distribution, and more sustainable and healthier practices (IPES-Food, 2016). One core example is the vested interests of large companies that produce pesticides and chemical inputs.

5.3.2.2 Meeting climate goals while maintaining nature and nature's contributions to people

Framing the Problem

Under a business-as-usual scenario, global demand for land is projected to increase substantially. An expansion of agricultural land and bioenergy plantations may leave little room for preserving natural habitats and biodiversity (Secretariat of the Convention on Biological Diversity, 2014). Many more stringent climate mitigation scenarios (reaching 450 ppm but also 550 ppm CO_2eq concentrations by 2100) rely on large-scale deployment of bioenergy with carbon capture and storage (BECCS) (Rogelj *et al.*, 2018b; Smith *et al.*, 2014). The bioenergy crop area required by 2100 is estimated at 150 to 600 Mha (Rogelj *et al.*, 2018a). Potential implications for biodiversity have been explored (Meller *et al.*, 2015), but only a few global bioenergy scenario studies explicitly addressed biodiversity targets and SDGs (e.g., Beringer *et al.*, 2011; Erb *et al.*, 2012; Heck *et al.*, 2018; Leclère *et al.*, 2018; see also 5.3.1.2). It has also been suggested that freshwater biodiversity is severely threatened by ongoing and future development of hydropower (Hermoso, 2017), but we are not aware of any global hydropower scenarios that explicitly address impacts on biodiversity and ecosystem services.

Global energy production from various bioenergy systems in 2018 generates about 50 EJ per year. In some regions, bioenergy production generates substantial economic benefits for states and increases employment and individual incomes (Smith *et al.*, 2014). Bioenergy production in scenarios reaching the 1.5° C target range from 40 to 310 EJ per year (Rogelj *et al.*, 2018b). Major bioenergy systems include industrial organic residues, forest and agricultural residues, dedicated biomass plantations and optimal forest harvesting. Dedicated biomass plantations include annuals (e.g., corn and oil crops), perennials (e.g., sugarcane, oil palm and perennial grasses) and wood-based systems such as short rotation woody crops (see Creutzig *et al.*, 2015; Smith *et al.*, 2014 for a more detailed classification.

Substantial climate mitigation potentials could also be generated by reducing demand for traditional biomass, which until recently accounted for ~80% of current bioenergy use and helps meet the cooking needs of

~2.6 billion people (Chum *et al.*, 2011; IEA, 2012). Ecosystem-based non-bioenergy climate mitigation also has substantial potential without adverse effects on biodiversity and food security. So-called 'natural climate solutions' include a wide range of measures, such as reforestation and changes in forest management, fire management, changes in fertilizer use in grasslands as well as coastal and peat restoration (Griscom *et al.*, 2017). But all such solutions have adverse effects, so scenarios are key for considering trade-offs in context.

Land-based climate mitigation scenarios achieving multiple sustainability goals

Global bioenergy potentials and scenarios are commonly generated with Integrated Assessment Models (IAMs), which explicitly account for competing land demands (Rogelj *et al.*, 2018b), and are consistent with estimates from other global biophysical modelling approaches (Beringer *et al.*, 2011; Erb *et al.*, 2012; Heck *et al.*, 2018; Kok *et al.*, 2018; Meller *et al.*, 2015). BECCS from dedicated plantations in accordance with SSP2 and RCP2.6 would most likely lead to a further transgression of planetary boundaries for land-system change, biosphere integrity and biodiversity, and biogeochemical flows (Heck *et al.*, 2018). So-called second- and third-generation bioenergy systems (IEA & FAO, 2017), such as the use of agricultural residues, and biofuels produced from lignocellulosic ethanol and algae, often have a lower impact on biodiversity and the environment in general. An interpretation of the SSPs with five IAMs with distinctive land use models suggests substantial potential for climate mitigation through improved agricultural management and second-generation bioenergy crops in combination with BECCS, while preserving or even enhancing the extent of natural ecosystems and carbon stocks, in particular in an SSP1 world (Popp *et al.*, 2017).

However, in current models for large-scale scenarios, biodiversity targets have only been included in rather simplistic ways, such as an additional constraint for land allocation, e.g., excluding protected areas from bioenergy or food production (Beringer *et al.*, 2011; Erb *et al.*, 2012; Meller *et al.*, 2015). The global pathways (SSPs) and associated models still lack many processes important to quantify changes in habitat quality and biodiversity (Harfoot *et al.*, 2014; Meller *et al.*, 2015), particularly at local scales (Kok *et al.*, 2017), implying high uncertainty in future impacts of large-scale deployment of bioenergy systems on biodiversity and ecosystem services (Meller *et al.*, 2015).

Griscom *et al.* (2017) estimated that 'natural climate solutions' can provide 37% of the climate mitigation needed until 2030 for a better-than 66% chance of reaching the 2 degrees Celsius target, without adverse effects on biodiversity and food security, and with likely co-benefits for biodiversity. Carbon storage, climate mitigation effectiveness and biodiversity can, for example, be promoted if trees are allowed to grow older in certain temperate forests (e.g., Law *et al.*, 2018). Results from a global analysis, however, suggest that optimal forest harvest ages in terms of climate mitigation efficiency (including life-cycle analyses) often deviate from those ages that promote biodiversity the most (Oliver *et al.*, 2014) and high biodiversity is often found in low-biomass systems (Bond, 2016; Myers *et al.*, 2000). Abreu *et al.* (2017), for example, found strong negative effects of fire suppression on plant and ant richness in the savannahs of the Brazilian Cerrado, a global biodiversity hotspot, where carbon storage was increased by fire suppression. Nevertheless, a recent study with a global integrated energy-economy-land-use modelling system including a wide range of climate mitigation activities suggested that it is feasible to reach the 2 degree Celsius and even the 1.5 degree Celsius target of the Paris Agreement, with co-benefits for air quality, food and energy prices, and without substantial negative effects on biodiversity (Bertram *et al.*, 2018). These outcomes were achieved via a reduction of agricultural trade barriers, no further increases in first-generation biofuels, an increase in the protected forest area and an increase in carbon pricing (Bertram *et al.*, 2018). 'Bending the curve' scenarios also suggest substantial potential for improved land management and synergies between climate mitigation and biodiversity, but also trade-offs (see section 5.3.1.2, **Box 5.3** and Kok *et al.*, 2018).

Synthesis and open questions about climate mitigation pathways

Different bioenergy systems can have very different impacts on biodiversity and ecosystem services (Meller *et al.*, 2015). Intensively managed bioenergy monocultures, such as sugarcane, maize/corn, soybeans, and oil palm have roughly similar negative impacts as other forms of intensive agriculture on biodiversity and ecosystem services more broadly, which raises concerns about their future deployment. The global potential of second- or third-generation bioenergy systems is more uncertain than the above first-generation systems. Alternatively, establishing bioenergy systems that integrate multiple functions can also promote biodiversity (Creutzig *et al.*, 2015; Meller *et al.*, 2015). For example, when combined with agroforestry or installed on degraded land, oil palm plantations can generate co-benefits on food production, carbon storage and biodiversity (Creutzig *et al.*, 2015; Smith *et al.*, 2014). It has also been suggested that marginal and degraded lands, currently not used for food production, might have a substantial potential for bioenergy production. However, how much land is available or unused has been debated (Creutzig *et al.*, 2015), and many areas considered marginal in terms of their agricultural or forestry potential harbour rich biodiversity (Bond, 2016; Myers *et al.*, 2000). Also, 'low-input high-diversity' (LIHD) mixtures of native grassland perennials, for example, can have higher energy yields than monocultures, increase carbon storage in soils, benefit biodiversity and ecosystem services, and they can be grown on agriculturally degraded soils (e.g., Tilman *et al.*, 2006b). Even for the European Natura2000 protected area network, a large potential of low-input high-diversity bioenergy production has been suggested (Van Meerbeek *et al.*, 2016). However, intensively managed monocultures often have higher yields and are, therefore, favored by current price and policy incentives, even though they perform poorly when considering multiple ecosystem services (e.g., Werling *et al.*, 2014). Forest residue use also has large potential, but it can also decrease old-growth forest structures, such as deadwood, which are important habitats for many species (Meller *et al.*, 2015).

Large-scale deployment of intensively managed first-generation monoculture bioenergy crops would have profound negative impacts on biodiversity and many ecosystem services but a comprehensive quantification of such effects at the global scale is missing. A recent study concluded that a low-emission scenario with BECCS might affect global vertebrate diversity as negatively as a high-emission scenario with stronger climate change but without BECCS (Hof *et al.*, 2018). Nevertheless, substantial additional potential for bioenergy exists without compromising biodiversity and ecosystem services, but the implications of different bioenergy systems for a variety of ecosystem services and sustainable development are often poorly captured in scenario studies.

Other ecosystem-based climate mitigation activities surely also have large potential for sequestering carbon cheaply while providing multiple ecosystem services, and boosting biodiversity (Griscom *et al.*, 2017). It is, however, difficult to generalize under which conditions certain management actions preserve biodiversity and achieve an optimal supply of several ecosystem services. Optimal approaches (balancing trade-offs of production and conservation) are region- and ecosystem-specific and include considerations of both biological and livelihood diversity. For instance, among the guiding principles proposed to maximize carbon storage and commercial forestry in landscape restoration schemes in the tropics is that afforestation should not replace native grasslands and savannahs (Brancalion & Chazdon, 2017).

The reviewed literature suggests that governance and shifted economic incentives will be necessary to promote the development of those land-based climate mitigation activities that secure multiple ecosystem services (Grubler *et al.*, 2018; IEA & FAO, 2017; van Vuuren *et al.*, 2015; Werling *et al.*, 2014). Demand-side climate mitigation measures, e.g., reduced waste or demand for energy and livestock products, are often more likely to achieve multiple goals, such as greenhouse gas emission reduction, food security and biodiversity protection than bioenergy plantations (Grubler *et al.*, 2018; Smith *et al.*, 2013). Low energy demand pathways, with reduced or no reliance on BECCS, would likely result in significantly reduced pressure on food security (Roy *et al.*, 2018). Some demand-side changes will require life-style changes, which can take more time than supply-side measures and pose challenges to influence by policies (Smith *et al.*, 2013; see also section 5.3.2.1 and 5.4.1.2 on consumption). However, current observable trends suggest a substantial potential to decrease the global energy demand despite rises in population, income and activity. A global scenario study based on these trends suggest that the 1.5 degrees Celsius target and many SDGs could be met without relying on negative emission scenarios (Grubler *et al.*, 2018), but most global studies concluded that some negative emissions might still be necessary even with optimistic assumptions concerning, e.g., lifestyle changes, reforestation and energy transitions (e.g., van Vuuren *et al.*, 2018). Further transdisciplinary research and improved models for ecosystem management and bioenergy scenarios are, however, necessary to close the knowledge gaps outlined above.

5.3.2.3 Conserving and restoring nature on land while contributing positively to human well-being

Framing the problem

The concept and practice of protected areas (PAs) has been at the heart of conservation policy since its inception in the 19th Century. Traditionally, PAs were implemented by governments using strict conservation approaches, which treated biodiversity protection as incompatible with social-cultural practices and benefits. By the 1980s, classic conservation models evolved towards more participatory management and inclusive conservation approaches. The Convention of Biological Diversity (CBD) called for the protection of at least 17% of terrestrial and inland water by 2020, especially areas of particular importance for biodiversity and ecosystem services (a target nearly met, although with limited spatial and ecological representativeness; chapter 3).

Existing PAs suffer from several challenges. Isolated areas can lack functional connectivity for species. Some authors argue that biodiversity within PAs continues to decline, questioning the effectiveness of current conservation management approaches (Coad *et al.*, 2015), while other studies document the effectiveness of PAs, at least relative to other land uses (Gray *et al.*, 2016). Today's PAs are likely not adequate to conserve many species whose distributions will shift due to climate change (Secretariat of the Convention on Biological Diversity, 2014); they may also suffer from additional degradation (e.g., increased fire risk). In this context, to protect habitats and species and maintain connectivity, attention has been directed towards biodiversity-rich land under **private** ownership and under the governance and management of IPLCs, who already contribute to the management of around 40% of PAs globally (Drescher & Brenner, 2018; Garnett *et al.*, 2018; Kamal *et al.*, 2015; Maron *et al.*, 2018; Paloniemi & Tikka, 2008; Tikka & Kauppi, 2003).

In addition to conservation, **restoration** of ecosystems and landscapes (although in its early stages) is rapidly becoming a new major driver of changes in nature and NCP (Aronson & Alexander, 2013). Aichi Biodiversity Target 15 together with the "Bonn Challenge"—a global restoration initiative—have established a goal of restoring 150 million hectares of deforested and degraded land globally by 2020. The New York Declaration on Forests expanded this goal to 350 million hectares restored by 2030 (Chazdon *et al.*, 2017). In addition, several large-scale restoration initiatives have recently emerged around the world (Latawiec *et al.*, 2015).

What do scenarios say about how to achieve these goals?

Sustainability-oriented global scenarios usually consider the maintenance or expansion of protected areas (PA) networks as central. For instance, the Rio+20 target-seeking scenarios implemented three different assumptions regarding the extent and distribution of PAs. The Global Technology pathway, reflecting a land-sparing approach, explores the expansion of agricultural areas close to existing agricultural areas, and assumes that 17% of each of 7 biodiversity realms will be protected in PAs situated far from agriculture. In the Decentralized Solutions pathway, production areas are shared with nature elements covering at least 30% of landscapes to reinforce PAs, which cover 17% of all 779 ecoregions. As previously discussed, Kok *et al.* (2014) show that both strategies may reduce biodiversity loss, but the biodiversity preserved, and the spatial distribution of losses differ greatly (see **Box 5.1**).

Any approach entails international cooperation including funding from different sources (e.g., Global Environment Facility, Butchart *et al.*, 2015) to facilitate and scale up protected areas. This is especially true in developing regions facing challenges to effective protection in current and future protected areas. Scenarios at local and national scales emphasize, as a critical element of pathways, the improvement of monitoring systems and the enforcement (and protection) of environmental legal frameworks (Aguiar *et al.*, 2016).

Also, at local to regional scales (Appendix 5.2), scenarios show that **existing protected areas are at risk**, mostly due to political changes, incomplete implementation and institutional weaknesses (see chapter 3 for a discussion). In Latin America, for instance, the network of PAs and indigenous lands is one of the most important factors managing the Amazon deforestation frontier (Aguiar *et al.*, 2007; Pfaff *et al.*, 2015; Soares-Filho *et al.*, 2010). However, these areas suffer the impacts of illegal logging and fires, and are threatened—above all—by political and economic pressure to give way to agricultural expansion, major infrastructure and natural resource extraction projects (Aguiar *et al.*, 2016; Ferreira *et al.*, 2014).

The **expansion of protected areas networks** faces competition with other land uses. In a global analysis, Venter *et al.* (2018) found that both old and new protected areas did not target places with high concentrations of threatened vertebrate species, but instead appeared to be established to lessen conflict with agriculturally suitable lands. In Africa, for instance, although the need for expanding protected area networks is great, some authors argue that improved governance of existing PAs may provide more biodiversity benefits (Costelloe *et al.*, 2016).

Local scenarios propose a combination of protected areas and land-sharing approaches through landscape planning. The 'land sharing' strategy has the potential to improve connectivity between natural areas by boosting natural elements within the agro-ecological matrix. Meanwhile, increasing productivity reduces the land area needed for agricultural production and consequently reduces biodiversity loss. But the sustainability of that intensification depends on reserving large areas within the agro-ecological matrix for natural elements (Perfecto & Vandermeer, 2010).

The **spatial arrangement** of protected areas and natural elements also matters, as explored by landscape planning to meet human needs via multiple ecosystem services while maintaining biodiversity in functioning ecosystems. This can be done on private lands, optimizing trade-offs between environmental, social and economic benefits (Kennedy *et al.*, 2016; Seppelt *et al.*, 2013). Such planning can also consider the importance of mosaics of diverse governance types and the overlap of PAs with Indigenous lands and community-governed conservation areas that can enhance opportunities to meet human needs and ecosystem function. In the Andes, for instance, the spatial and temporal organization of farms and agricultural practices at multiple scales—including some agroforestry practices—could improve yield and boost ecosystem services (Fonte *et al.*, 2012).

Restoration

Ecosystem restoration can also deliver multiple benefits to people and help achieve multiple Sustainable Development Goals (Possingham *et al.*, 2015). Successful cases of restoration are found all over the world (see Fisher *et al.*, 2018). Achieving these targets would ease pressing global challenges such as climate change mitigation (Chazdon *et al.*, 2016) and adaptation (Scarano, 2017), and biodiversity decline (Crouzeilles *et al.*, 2017). Large-scale restoration may play a critical role in enhancing nature's contributions, but it represents yet another competing use of already scarce land resources with potential impacts on local livelihoods (Adams *et al.*, 2016; Hecht *et al.*, 2014).

Box 5 4 Restoration experiences in Brazil.

Brazil provides valuable case studies for understanding potential solutions and challenges of accommodating new restoration areas where land is an increasingly limited resource (Latawiec *et al.*, 2015). The State of Espírito Santo government, supported by both agricultural and environment departments, has been promoting large-scale forest restoration and conservation programs through the 'Reforest' Program ('Reflorestar' in Portuguese) with a total goal of approximately 236 000 ha between 2005 and 2025. At the same time, the State's development plan aims to expand agricultural areas by 284 000 ha and forest plantations by 400 000 ha. The current pasture productivity in the State is less than one third of its potential (Latawiec *et al.*, 2015). Pasturelands therefore provide an opportunity to accommodate both intensified but non-confinement-based cattle ranching activities and restoration, through land sparing **(Figure Box 5.4.A)**.

A second example is from the state of Sao Paulo, where the Rural Landless Workers' Movement redistributed more than 3000 families to settle in the Pontal do Paranapanema in 1942, in the Reserva do Pontal area designated to protect the highly threatened Atlantic Forest ecosystem and the endangered endemic black lion tamarin (Hart *et al.*, 2016; Valladares-Padua *et al.*, 2002). A concerted effort by a range of stakeholders supported rural livelihoods through landscape-level coordination, developing sustainable agroforestry initiatives and creating ecological corridors to connect forest fragments (Wittman, 2010). Diversified agroforestry created a buffer for wildlife reserves and improved agricultural productivity, increasing incomes for local communities (Cullen *et al.*, 2005). This example demonstrates that implementation of a landscape approach wherein a participatory approach can facilitate forest conservation and restoration. Such integrated landscape management approaches have gained prominence in the search for solutions to reconcile conservation and development (Sayer, 2009), particularly if they consider nonlinear ecosystem dynamics and climate change (Sietz *et al.*, 2017).

Figure 5 4 A **An example of land sparing.**

An increase in pasture productivity in areas suitable for cattle ranching (left) allowed a farmer to set aside marginal areas with rocky soils (right) for forest restoration in the Atlantic Forest in Brazil (Latawiec *et al.,* 2015). Photo credit: Veronica Maioli.

These examples reveal several essential conditions for land sparing to occur, such as covering implementation costs, providing technical assistance, and setting up rigorous monitoring to avoid leakage and rebound effects. It is also paramount to protect local livelihoods involved in other farming activities that may be less profitable but key to meeting local and regional food security needs (e.g., production of staple crops such as black beans, in the case of Brazil). As illustrated by first São Paulo example, sometimes leakage might be best avoided by diversifying production systems through land sharing (Perfecto *et al.*, 2009).

Demand for agricultural land and land for restoration will continue to grow for several decades, putting pressure on scarce land resources (Smith *et al.*, 2010). This pressure can be mitigated, however, through solutions promoting more sustainable and inclusive land management. In particular, integrated land-use planning that takes into account conservation and restoration priorities with priorities for increased agricultural production (Margules & Pressey, 2000; Strassburg *et al.*, 2017) might play a key role in reconciling competing demands.

Conservation and restoration scenarios and IPLCs

Few of the aforementioned scenarios directly address the interplay between human well-being, nature conservation and restoration goals. It is primarily at local scales that studies suggest that engaging meaningfully with IPLCs—whose lands hold much of the world's biodiversity—is one of the most effective ways to secure biodiversity conservation and sustainable use (FPPIIFB & SCBD, 2006). The global importance of IPLCs is treated in chapters 1, 2, and 3.

Empowering IPLCs as central partners in conservation and climate-change mitigation has allowed many people to gain access to land and citizenship rights (chapters 3 and 6; Kohler & Brondizio, 2017), but this has provided limited improvements in access to social services and economic opportunities. On the other hand, Kohler and Brondizio (2017) suggest that public policies and conservation programs should not delegate responsibility for managing protected areas to IPLCs without considering local needs, expectations and attitudes toward conservation.

It is primarily at local scales that scenarios explicitly consider land tenure rights, economic incentives and alternatives, and vulnerability of IPLCs (living inside or outside protected areas and other special units; e.g., Folhes *et al.*, 2015). For example, in **China**, Cotter *et al.* (2014) considered a GoGreen scenario that embedded the MAB (Man and the Biosphere Programme) principles of conservation and sustainable livelihoods while introducing Traditional Chinese Medicine agroforestry. This GoGreen scenario enabled protection of forests while sustaining rural livelihoods. Similarly, Suwarno *et al.* (2018) concluded that the current forest moratorium policy (BAU) is not effective in reducing forest conversion and carbon emissions. Furthermore, they suggested that a policy combining a forest moratorium with livelihood support and increases in farm-gate prices for forest and agroforestry products could increase local communities' benefits from conservation (including via certification schemes for cocoa production). Elsewhere, Mitchell *et al.* (2015) employed social-ecological modelling and scenario analysis to explore how governance influences landscape-scale biodiversity outcomes in the **Australian Alps**. Their study highlighted the importance of shared values and attitudes supportive of conservation, as well as political will and strategic direction from local governments.

Finally, some scenarios also explicitly mention the importance of **using biodiversity products to create economic alternatives** for IPLCs and regional economies (Aguiar *et al.*, 2016; Folhes *et al.*, 2015). A recent paper (Nobre *et al.*, 2016) brings a broader proposal: a new development paradigm that transcends reconciling conservation with intensification of agriculture, moving towards biomimicry-based development—a "Fourth Industrial Revolution" that could benefit IPLCs and the world at large.

Synthesis and open questions about conservation and restoration pathways

The expansion of the current PA network is necessary to ensure that PAs are ecologically representative and connected, including in light of climate change. However, to accommodate conservation and restoration where land is increasingly limited, the reviewed literature points out that **participatory spatial planning based on a landscape approach** is key. The landscape approach aims to allocate and manage land to achieve social, economic, and environmental objectives in landscape mosaics where multiple land uses coexist. Such integrated management should also include the urban-rural interface, and the importance of locally desirable livelihood activities less profitable than industrial agriculture, but key to meeting local and regional food security needs.

On the other hand, many existing PAs are not effectively managed or adequately resourced. The review of the current scenario literature, especially at local to national levels, underlines the need to **protect the protected areas**, including by enhancing monitoring systems and legal frameworks.

Sustainable-use protected areas (and other special areas, such as indigenous lands) will rest upon **appropriate governance mechanisms and collaboration with IPLCs.** This would begin with recognition of IPLC knowledge and leadership including via novel compensation-oriented payments for ecosystem services programs (5.4.2.1), but it also might involve economic alternatives, technological innovations, and access to markets and basic services (education, health, etc.). On the other hand, IPLCs should not be seen as "traditional environmentalists" to whom the responsibility to manage protected areas is delegated, but rather an opportunity to co-govern with those who have intimate and ancestral-derived knowledge and practices, but also varying needs in different contexts. Finally, innovations related to the benign industrial use of biodiversity could benefit local populations and regional economies, and contribute to conservation.

Mechanisms to facilitate and scale up international **financing of protected areas** are also essential, especially in developing regions. However, funding is not enough, as weak governance and power structures in different regions need to be taken into account. **Power asymmetries**, especially in developing countries, threaten not only legal frameworks (for instance, regarding protected area networks), but also the possibility of implementing integrated management processes.

5.3.2.4 Maintaining freshwater for nature and humanity

Framing the problem

Maintaining freshwater for nature and humanity is an urgent challenge, with an estimated 1.8 billion people likely to live under conditions of regional water stress (Schlosser *et al.*, 2014). The diversion of freshwater for human use has been characterised by an incomplete appreciation of freshwater ecosystems and the services they provide. Aquatic ecosystems in some cases have been losing species up to 5 times faster than other ecosystems (Ricciardi & Rasmussen, 1999), and the situation is set to worsen as anthropogenic pressures on water resources increase (Darwall *et al.*, 2008; Dodds *et al.*, 2013; Dudgeon *et al.*, 2006). Anthropogenic land-cover change is a more dominant driver of hydrological impacts than climate change (Betts *et al.*, 2015), and global-scale population and economic growth variables have greater effects on projected water supply-demand relationships than does mean climate (Vörösmarty *et al.*, 2000). Climate change is a major driver of agricultural water demand, however, primarily through increased temperature, which increases the transpiration demand; effects due to changes in precipitation and runoff are variable and uncertain (Turral, 2011).

Around 2010, food production accounted for 70-84% of global water consumption, and dominated projected consumption (FAO, 2016; Secretariat of the Convention on Biological Diversity, 2014). Implementation of the OECD baseline scenario for 2050 in modelling biodiversity “intactness” of freshwater ecosystems (Janse *et al.*, 2015) indicates further global declines in aquatic species richness, particularly in Africa. In 2014, freshwater fish (a major livelihood component and economic sector) constituted 12.7% of the global capture fishery, and 64% of aquaculture fish (FAO, 2016; McIntyre *et al.*, 2016). Access to fish by IPLCs is being eroded by changing legal frameworks and commodification (Allison *et al.*, 2012; Beveridge *et al.*, 2013), as well as pollution and overfishing. Freshwater and associated fish are critically limiting resources on many small island nations. In the Polynesian islands, as one example, major threats to freshwater biodiversity relate mainly to alteration of natural flow regimes (barriers and abstraction of water), plus overharvesting, alien species and climate change (Keith *et al.*, 2013).

Water for energy production accounted for approximately 15% of global withdrawals in 2010 (Flörke *et al.*, 2013). Fricko *et al.* (2016) found that “once-through” cooling was the dominant source of withdrawals, and of thermal pollution in thermal power generation. Meeting targets for a stable global climate through the development of renewable energy puts additional stress on freshwater systems, because hydropower is considered a major renewable energy source. Changes in river flood pulses (sensu Junk, 1989) and water quality induced by dams have had adverse effects on biodiversity, ecological productivity (e.g., Abazaj *et al.*, 2016; Arias *et al.*, 2014) and sediment transport, by decreasing wet season flows, increasing dry season flows, impeding movement of aquatic life, and trapping sediments.

Changes in land cover in catchments affect river flow characteristics. Evidence for increased run-off from deforestation is clear (Zhang *et al.*, 2017), whereas the effects of afforestation are ambiguous (Jackson *et al.*, 2013; Vanclay, 2009). Clearly there are important trade-off implications for the carbon mitigation potential of afforestation. Land and terrestrial water management also poses a serious threat to the freshwater-marine interface (Blum & Roberts, 2009). Lotze *et al.* (2006) analysed 12 temperate estuaries and coastal seas, and found that about 40% of species depletions and extinctions could be attributed to habitat loss, pollution, and eutrophication. Other important consumers of water are industries, of which mining is particularly important in terms of demand and impacts (pollution, sediment load; Azapagic, 2004; Vörösmarty *et al.*, 2013; chapter 2).

Here we summarise characteristics of pathways towards resolving these tensions and challenges at global, regional and local levels, and draw out commonalities and differences across these scales. People use water to supply domestic and urban needs, to produce food, and to produce energy. These uses consume water, change its quality, and change associated contributions to people. Most normative scenarios relating to water have focused on improving water supply and quality for human purposes. In recent years, freshwater policies “have begun to move away from a riparian rights focus … towards efficiency improvements and river basin management” (UNEP, 2002). At the global scale, this shift is reflected in the global scenario analyses, as outlined below.

What do scenarios say about how to achieve these goals?

The GEO-3 “Policy First” scenario (UNEP, 2002) emphasizes using top-down governmental policy and institutional instruments to create integrated resource management approaches, including increased environmental stewardship. This scenario also invests in governance focused on social environmental policies, and enables greater participation from the private sector. The “Sustainability First” scenario describes pathways grounded in both government and civic society taking action against declining global social, economic and environmental indicators. The pathways incorporate greater collaboration between actors, with initiatives from society pushing sustainability. They also rest on positive media engagement, incorporation of research and analysis, and increased accountability and transparency. Greater integration of regional policies related to water management and other transboundary issues are envisioned.

The GBO-4 (CBD, 2014) re-assessment of the PBL (2012) Roads from Rio+20 used the same 3 scenarios designed to attain SDG targets, but with metrics addressing Aichi Biodiversity Targets relating to inland waters. Elements of all three scenario pathways address the maintenance of freshwater ecosystems and their multiple contributions. Aside from the systemic integration of freshwater nature into planning, development and communications, GBO-4 pathways include national accounting of water stocks. Specifically, in these pathways IPLCs are involved in creating and governing protected areas (PAs), PA networks are expanded to be more representative of freshwater ecosystems, and protection is enhanced for river reaches upstream and downstream of terrestrial PAs to maintain connectivity. These pathway elements were echoed strongly by Harrison *et al.* (2016). GBO-4 included a range of other elements, including management of pulsed systems that protects refugia for aquatic biota, identification of systems important for providing multiple ecosystem services (including disaster risk reduction); reduction of pressures on wetlands, river and mountain areas, and restoration of degraded systems. Policy instruments include the enforcement of environmental regulations for development projects, and new market instruments (wetland mitigation banking, payments for ecosystem services).

Pathways for food and freshwater

Pathways towards sustaining freshwater ecosystems and their multiple contributions rest on addressing **land use**, **eutrophication** and **hydrological disturbance**. The World Water Vision (Cosgrove & Rijsberman, 2000) identified two critical pathway elements: 1) limiting expansion of agricultural land area (requiring improved water use efficiency and agronomy) and 2) increased storage, through a mix of groundwater recharge, wetlands, alternative storage techniques employing ILK, and dams that minimize disruption of flow regimes and impacts, including on IPLCs.

Pathways for energy, climate and freshwater

Fricko *et al.* (2017) found significant potential gains from technological improvements in cooling. Transitioning toward air and sea-water cooling over the period 2040-2100 could reduce cumulative freshwater withdrawal by 74%, consumption of freshwater by 19% and thermal pollution by 41%. In addition, a rapid scale-up of non-water based renewable energy generation (wind, solar) could generate multiple co-benefits, including climate stabilisation, reduced water demand, improved water quality and a reduction in hydrological disturbance, sustaining fluvial ecosystems. In the Gulf States, cogeneration (using thermal energy from electricity generation to desalinate seawater) is responsible for about 85% of desalination (El-Katiri, 2013).

Flow alteration and barriers were not explicitly addressed in the global scenario pathways assessed here. At local and regional scales, studies suggest that improving environmental legislation (Fearnside, 2015), enhancing existing infrastructure (Zwarts *et al.*, 2006), and implementing operating procedures to minimise downstream ecological impacts (Kunz *et al.*, 2013) are critical pathway elements for conserving freshwater systems and their contributions. Demand management (advocated in GEO-3 and other meta-analyses) is also a central recommendation, including improved water use efficiency, pricing policies and privatisation.

In freshwater system pathways, there are some synergies between conserving nature and NCP and mitigating climate change: restoring and avoiding further conversion of peatlands is an important pathway element (Griscom *et al.*, 2017).

Regional and local perspectives

Sub-Saharan **Africa** is expected to experience one of the largest increases in point-source pollution of freshwater due to increasing urbanization and slow development of sewage treatment (Nagendra *et al.*, 2018). Investment in wastewater treatment is crucial to complement improved sewage reticulation (van Puijenbroek *et al.*, 2015), while investment in distribution infrastructure and improved regulation of access are pathway elements to ensure equitable access to water (Notter *et al.*, 2013).

Improvement of infrastructure across the continent is needed to increase agricultural production, while improved irrigation efficiency needs better enforcement of regulations (AfDB, 2015; Notter *et al.*, 2013). In the Inner Niger Delta, Zwarts *et al.* (2006) found that improving efficiency of existing water infrastructure, instead of building new dams, would improve conservation of ecosystem services and economic growth. In southern Africa a number of studies indicate that participatory approaches to water resource planning and environmental flows could enable equitable trade-offs between water users (Brown *et al.*, 2006; King *et al.*, 2014, 2003). Operating procedures for existing hydropower dams can be optimised to reduce biogeochemical impacts downstream (Kunz *et al.*, 2013).

In the Americas, issues arising from hydropower developments have identified elements of pathways towards sustainability (Moran *et al.*, 2018). In the Brazilian Amazon, unrepealed legacy legislation has allowed the overriding of environmental licensing laws; institutions and legal instruments, and full disclosure and democratic debate on river basin development plans are critical pathway elements, especially for transboundary river systems (Fearnside, 2015; Latrubesse *et al.*, 2017). At the local level in the Brazilian Amazon, key pathways include strengthening the capacity of local communities to negotiate with developers and develop management skills for collective projects (Folhes *et al.*, 2015).

Social-ecological systems modelling by Mitchell *et al.* (2015) in south-eastern Australia in the **Asia and the Pacific** region indicates that conservation of alpine lakes, fens and bogs would be enhanced by adoption of a long-term governance regime immune to short-term political agendas.

In **Europe and Central Asia**, a participatory backcasting scenario planning process for Biscay in the Basque Country found that water supply and water regulation could be optimised under their "TechnoFaith" scenario—one which prioritizes technological solutions. The "Cultivating Social Values" scenario achieved almost the same results through participatory decision-making, emphasis on local government, responsible consumption, and a proactive society (Palacios-Agundez *et al.*, 2013).

Synthesis about freshwater pathways

The scenarios literature reviewed above coupled with broader literatures on freshwater systems and management suggest the following key elements of sustainable pathways. A central cross-cutting conclusion is that sustenance of freshwater ecosystems and their contributions requires healthy catchment areas, careful allocation of water rights and maintenance of hydrologic variability (Aylward *et al.*, 2005; Dudgeon, 2010; Durance *et al.*, 2016; Harrison *et al.*, 2016; Kuiper *et al.*, 2014; Poff, 2009; Postel & Thompson, 2005). **Foremost among pathway elements is the importance of dynamic and iterative deliberations among stakeholders** in identifying desired futures and policy to achieve these (Tinch *et al.*, 2016).

Freshwater production as an ecosystem service: The pathways reviewed secure sustained supply of good quality water sufficient for human and environmental needs. This requires protection of upstream catchment areas, middle-reach floodplain systems (Green *et al.*, 2015) and often land rehabilitation to reinstate storage and reduce erosion and sediment transport. Such efforts can be broadened to regional and continental institutional arrangements to address the impacts of land-use change at basin scales (Ellison *et al.*, 2017). Explicit recognition of the provisioning function of upstream catchments is crucial for land-use planning, a central element of sustainable pathways. Design strategies for forested catchment land cover, such as (re)planting water courses with indigenous species can also produce natural hydrographs and high-quality water (Ferraz *et al.*, 2013; Vanclay, 2009). Integration of surface and groundwater management (Giordano, 2009) reduces the need for dams. Catchment protection (e.g., limiting mining and industry) can reduce pollution of water-producing areas.

Freshwater systems: There is strong consensus that variability in hydrological regime is crucial for maintaining freshwater ecosystems and their contributions to society, as central in sustainable pathways (e.g., Annear *et al.*, 2004; Biggs *et al.*, 2005; Bunn & Arthington, 2002; Poff *et al.*, 1997, 2010; Postel & Richter, 2003). Sustainable pathways maintain or re-instate flow variability, quantity, timing and quality needed to sustain healthy freshwater systems. Pathway element include: i) slowing and reversing catchment land cover transformations (deforestation, intensive cultivation); and ii) minimising disruption of flow regimes by using fewer, smaller dams.

Agricultural production: Attaining ambitious pathway targets for agricultural production (see section 5.3.2.1 Feeding Humanity) without damaging freshwater nature entails a broad set of actions. Optimising water use for agricultural production rests on sustainable intensification, improved management through technology, better agronomy, and improved hydrological governance, including implementation of "green water" techniques (Bitterman *et al.*, 2016; Pandey *et al.*, 2001; Rockström & Falkenmark, 2015). Also important are improved management to reduce non-point source pollution (e.g., Hunke *et al.*, 2015) and sediment input to freshwater systems, and enforcement of standards and allocations.

Energy production: The production of hydropower—central to many sustainable pathways—carries many impacts which cannot be mitigated (e.g., Fearnside, 2015; Kling *et al.*, 2014). Reductions in variability, discharge and changes in biogeochemistry are among these. Alternative sources of renewable energy are implementable with present technology. Management regimes of existing hydropower dams can be optimised by integrating ecological requirements of variability and water quality into standard operating protocols (Kunz *et al.*, 2013).

Supply chains: Sustainable pathways require that supply chains secure sufficient water to meet environmental demands, human rights and needs. This can be achieved by a combination of improved valuation of the resource (demand management), involving stakeholders inclusively, and investment in infrastructure, such as dual reticulation systems for urban supply, treatment systems for urban waste water and agricultural waste water. Dedicated institutional arrangements for managing river basins are seen as a critical component for managing supply chains.

Consumer actions: Reduction of consumption and waste as a key pathway element can be achieved by optimising efficiency in urban use, agricultural use (precision irrigation, improved agronomy, reduced waste flows), industrial/mining use (tertiary treatment of waste, increased regulatory oversight) and the energy sector (transition to alternative renewables, and cooling systems). Such actions are not likely to be made without changing incentives (including water pricing) (5.4.1.1, 5.4.2.1), encouraging behaviour change including through infrastructure (5.4.1.3), and increasing awareness and knowledge among consumers (5.4.1.8).

5.3.2.5 Balancing food provision from oceans and coasts with nature protection

Framing the Problem

Seafood from fisheries and aquaculture is an integral part of the global food system, supplying approximately 17% of all animal protein consumed by humans and providing a suite of micronutrients important for human nutrition (FAO, 2016). The dietary importance of seafood is pronounced in many food-insecure regions (Béné & Heck, 2005; FAO, 2016). Demand for seafood is predicted to grow substantially in coming decades, potentially at a higher rate than other major sources of animal protein (Tilman & Clark, 2014), and failing to meet that demand may affect the health of millions of people (Golden *et al.*, 2016).

Broad limits to global marine fisheries production have been reached (Worm & Branch, 2012), while aquaculture production of aquatic animals has steadily increased over the past four decades. As of 2013, 31.4% of fish stocks evaluated by the FAO were determined to be overfished and 58.1% were fully fished (FAO, 2016); the former yield less food than is theoretically possible, and the latter cannot yield additional food without becoming overfished. While marine fisheries landings reported by the FAO have remained relatively steady since the mid-1990s, at ~80 million metric tons, aquaculture production increased from less than 10 million tons in 1985 to over 70 million tons, or 44% of the world's total seafood production, in 2014 (FAO, 2016). A recent reconstruction of global catches (including catch types excluded from the FAO data) indicate that the mid-1990s global maximum in catches was higher, and that the decline in the subsequent years has been more severe, than observed in the FAO data alone (Pauly & Zeller, 2016). While aquaculture avoids some of the ecological concerns of fisheries, concerns involve the conversion of coastal wetlands, particularly mangroves, for aquaculture (Ottinger *et al.*, 2016), and the use of the majority of the world's fish oil and fishmeal production for aquaculture feeds (Tacon & Metian, 2015).

Safeguarding and improving the status of biodiversity will entail reducing intensity of seafood production to levels that allow for sustainable use of living marine resources (Sumaila *et al.*, 2015; Worm *et al.*, 2009). Some efficiency improvements are possible, however, such as ensuring that food-grade fish are used for direct human consumption rather than for aquaculture or livestock feed (Cashion *et al.*, 2017). While indirect drivers such as demographic changes and consumption patterns increase pressures on marine biodiversity, these drivers also exacerbate other factors such as poor governance and poverty (Finkbeiner *et al.*, 2017). When fisheries resources are overexploited, actions to improve conservation status can also increase sustainable seafood production. However, conservation and fisheries rebuilding may affect the availability and access to living marine resources by specific human communities in the short-term, although effectively managed marine ecosystems can support long-term sustainable development (Costello *et al.*, 2016; Jennings *et al.*, 2016; McClanahan *et al.*, 2015). Involvement and participation of stakeholders and local communities and consideration of local traditions in decision-making and implementation of resource management and biodiversity conservation policies could help reduce trade-offs between seafood provision and biodiversity conservation (Berkes, 2004; Christie *et al.*, 2017; Uehara *et al.*, 2016). Meeting food provisioning objectives appears to entail conservation and/or restoration of marine ecosystems, reduction of pollution, management of destructive extractive activities, strong progress toward climate change targets, elimination of perverse subsidies, education and other aspects of capacity builiding (Teh *et al.*, 2017).

What do scenarios say about how to achieve these goals?

Available scenarios for marine biodiversity and ecosystem services focus on identifying and exploring pathways to achieve biodiversity conservation and sustainable seafood production goals across multiple spatial scales (Table SM 5.2.A). Specifically, these scenarios explore options for marine protected areas and fisheries management such as spatial planning and control of catches or fishing effort. Climate change and its effects on marine biodiversity and ecosystems are included in a few cases to examine how regional conservation and fisheries management goals can be achieved under global changes.

Marine pollution is a cross-cutting issue that is often implicitly included in scenarios related to multiple economic sectors. Some of these sectors are sources of marine pollution. Marine spatial planning processes are central, managing activities such as shipping and coastal development. With recent focus on plastic waste in the ocean (e.g., see chapter 4), scenarios have been developed for waste management to achieve targets for marine plastic waste (Löhr *et al.*, 2017). A variety of telecouplings were explored particularly in management of transboundary fish stocks (Carlson *et al.*, 2018). For example, different fisheries management measures in the high seas on straddling fish stocks were examined to investigate their effectiveness in reducing climate risk on coastal fisheries and biodiversity (Cheung *et al.*, 2017).

Regional to global scale scenarios often focus on examining a specific policy pathway, while multiple pathways are more commonly considered at subnational to national scales (Table SM 5.2.A and Figure SM 5.2.A). At large spatial scales, existing scenarios explored different extents and configurations of marine protected areas and their effectiveness in protecting biodiversity from impacts of multiple human activities, or management of fishing effort to maximize sustainable seafood production. Although these scenario pathways are not considered simultaneously, they may indeed be mutually compatible in comprehensive pathways to sustainability. In contrast, scenarios for smaller spatial scales often examine pathways to specific national or regional policy frameworks such as the Marine Strategy Framework Directive in the Europe Union or, more generally, ecosystem-based management. These policy frameworks involve multiple policy goals, e.g., biodiversity conservation, economic benefits, sustainable food production, and the viability of specific industries or sectors. Examining a portfolio of pathways and options to achieve these multiple policy objectives and their associated interactions and trade-offs could help inform ecosystem-based management of the ocean.

One of the linkages between marine biodiversity and sustainable food production goals that is most commonly explored in existing scenario analyses (specifically target-seeking/policy-screening) is pathways to achieve Maximum Sustainable Yield (MSY) and the implications for biodiversity (see 5.3.2.5). Although direct utility of MSY as a target for fisheries management has been widely criticized (Berkes *et al.*, 1998), MSY is explicitly stated as an aspiration in important international agreements and national policies such as the United Nations Law of the Seas and and the European Common Fisheries Policy. However, achieving ecosystem-level long-term average maximum production may lead to overexploitation or depletion of relatively less productive or less valuable populations (e.g., through bycatch), which has been suggested in scenario assessments at global, regional and local scales (Cheung & Sumaila, 2008; Walters & Martell, 2004; Worm *et al.*, 2009). In some heavily exploited systems, achieving maximum sustainable yield may require restoring ecosystems and rebuilding fish stocks, which would have co-benefits for biodiversity conservation (Cheung & Sumaila, 2008; Pitcher *et al.*, 2000). In some specific cases, overexploitation has resulted in structural change in fisheries social-ecological systems, resulting in more intense trade-offs between maximizing sustainable yield and improving biodiversity status (Brown & Trebilco, 2014; Hicks *et al.*, 2016). For example, in eastern North America, the rise of invertebrate fisheries (e.g., shrimp) after the collapse of Atlantic cod may be due to a shift from a predator-controlled system to a prey-controlled system (Baum & Worm, 2009). Because of the high productivity and economic value of the invertebrates, rebuilding of cod fisheries (a potential biodiversity or ecosystem target) may lead to reduced fisheries profits (a sustainable food production target).

Achieving marine protected area (MPA) targets should contribute positively to both biodiversity conservation and sustainable food production, although the extent of co-benefits would depend on timeframe, site selection, and design and effectiveness of the protected areas. Scenario modelling efforts for MPA targets focus strongly on site selection with a primary objective of biodiversity conservation. Across many contexts, scenario and modelling studies that evaluate different MPA designs and the pathway to achieving MPA targets generally suggest that MPA networks would benefit both biodiversity and fisheries in the long-term, particularly in overexploited ecosystems, in part because of demonstrated spillover effects by which effectively-managed MPAs boost fisheries in surrounding waters (Gill *et al.*, 2017). However, trade-offs often exist in the short-term because of the time lag in biological responses to protection relative to the immediate cost of losing resource use opportunities (Brown *et al.*, 2015). The degree of such trade-offs and co-benefits is shown to be sensitive to ecosystem and MPA attributes such as mobility of organisms, dispersal of the populations, size of and connectivity between protected areas (Gill *et al.*, 2017). In addition, scenario analysis, particularly those with stakeholders participation, often reveals trade-offs and conflicts between different sectors and communities in identifying pathways to achieve the MPA targets (e.g., Daw *et al.*, 2012). Climate change may further complicate the trade-offs between MPA designation and different sectors as range-shifts and habitat changes driven by climate change may add additional constraints on the design of

MPA network or require bigger MPAs (Fredston-Hermann *et al.*, 2018). On the other hand, scenario analysis at multiple scales could also help identify pathways to reduce or resolve such trade-offs (IPBES, 2016).

Scenario research has also identified co-benefits from addressing other non-fishing drivers such as climate change (and ocean acidification) and habitat degradation. Given the increased focus on ecosystem-based fisheries management (Link, 2010), recent scenario analyses explored multiple drivers that cut across marine biodiversity and sustainable food production, including environmental change drivers (e.g., climate, pollution and habitat degradation). Overall, clear co-benefits exist in addressing drivers of environmental change for both biodiversity conservation and fisheries production globally (e.g., Cheung *et al.*, 2016) and regionally (e.g., Ainsworth *et al.*, 2012; Sumaila & Cheung, 2015). Specifically, climate change is likely to trigger species turnover and decreased potential fisheries catches, which compromises both biodiversity conservation and food production (Cheung *et al.*, 2009; Worm *et al.*, 2009).

Resolving apparently competing targets in sustainability pathways appears to require other actions with co-benefits for each. For instance, addressing perverse incentives associated with subsidies is a key element of sustainable pathways, given its co-benefits for biodiversity and long-term food provision (Pauly *et al.*, 2002; Sumaila *et al.*, 2010). Outside of fisheries management, organic and inorganic pollution are doubly harmful, often leading to hypoxia and increased harmful contaminants in seafood (e.g., mercury). Thus, achieving targets that address these climate and pollution drivers is an important element towards achieving both biodiversity and food security targets. However, few scenario analyses explore the contributions of mitigating these drivers for achieving biodiversity and fisheries targets. This is particularly relevant for climate change mitigation given that reducing biodiversity loss and/or ensuring sustainable food production (e.g., by eliminating overfishing, protecting habitat, and protecting local access to seafood) could be cost-effective means to reduce the impacts of climate change (Gattuso *et al.*, 2015).

Synthesis and open questions about pathways for oceans

Conservation and restoration of marine ecosystems can contribute positively to meeting food security goals in the long-term (Singh *et al.*, 2018). Marine conservation includes effective management of fishing and other extractive activities, consideration of climate change mitigation and adaptation, and reduction of pollution and other human pressures on marine ecosystems. International conventions and agreements exist to facilitate the development of specific actions at regional and national levels to achieve specific conservation targets and goals (Rochette *et al.*, 2015). Ultimately, a portfolio of measures is often key to reduce pressures on marine ecosystems (Edgar *et al.*, 2014).

Scenarios rarely consider explicitly the co-benefits and interactions between meeting conservation and food security goals, particularly for vulnerable coastal communities (McClanahan *et al.*, 2015). Recent studies, mainly at regional to local scales, have started to explore conservation-food security interactions using scenario analysis **(Table SM 5.2 A)**. Initiatives are underway to further develop capacity for scenarios and models for marine biodiversity and ecosystem services, including collating global and regional datasets for drivers such as fisheries catch and oceanographic changes, e.g., the Fisheries and Marine Ecosystems Impact Model Intercomparison Project (Tittensor *et al.*, 2018). Specific actions being considered in pathways to achieve both conservation and food security goals include, for example, elimination of perverse subsidies, reduction in fishing capacity, alternative fisheries management, designation of marine protected areas and climate mitigations. However, given the increasing focus of international conservation efforts on large marine protected areas or co-management of natural resources beyond national jurisdictions, linking scenario exercises with global scale pathways would help elucidate co-benefits and trade-offs of conservation efforts with food security issues locally, nationally and globally.

5.3.2.6 Resourcing growing cities while maintaining the nature that underpins them

Framing the problem

Urbanization rates, while relatively stable within developed country contexts, are increasing at an unprecedented scale within developing countries of the Global South (CBD, 2012; Nagendra *et al.*, 2018). Urbanization is both the movement of people from rural to urban areas, and a function of population increases within these regions. Urban dwellers now exceed 50% of the global population, and by 2050, there will be 2 to 6 billion more of them (UN, 2012). Urbanization will drive land-cover change both within defined city boundaries and in the broader surrounding landscapes from which cities are resourced. City expansion into surrounding areas is happening more rapidly in developing countries, and population growth appears to be a key driver here. In developed country contexts urban growth and expansion is slower and more strongly correlated with GDP measures and economic growth (Seto *et al.*, 2011). Cities are major consumers of natural resources and are highly reliant on regulating functions provided by ecosystems. These resource and ecosystem dependencies can stretch over extensive areas and form the basis of telecoupled systems where trade flows of resources connect distant regions (Fang *et al.*, 2016). And despite trade flows, cities face real challenges to maintain crucial resources, including clean water (Schlosser *et al.*, 2014).

Rapid urbanization is driving extensive changes in land cover and land use. This landscape fragmentation alters biodiversity patterns and ecosystem functions (Aronson *et al.*, 2014; Foley *et al.*, 2005; McKinney, 2006; Miller & Hobbs, 2002). Growth within and on the margins of cities can overlap with areas of rich biodiversity and natural resources (Chapin III *et al.*, 1997; McDonald, 2008; Ricketts & Imhoff, 2003). Rapidly urbanizing cities in biodiversity hotspots (such as Cape Town, South Africa) are particularly vulnerable to extinction and loss (Holmes *et al.*, 2012; Seto *et al.*, 2012a).

There is a pressing need to understand the implications of loss of species and habitats in and around cities (Grimm *et al.*, 2008), in terms of ecosystem services, human well-being and equity issues. How cities are provisioned with ecosystem services now and in the future relates to the success reaching the SDGs, particularly SDG 11 (to make cities inclusive, safe, and resilient and sustainable) and SDG 15 (protecting, restoring and promoting the sustainable use of terrestrial ecosystems).

What do scenarios say about how to achieve these goals?

Local scenarios and pathways related to nature, urbanization and sustainable development

A wealth of biodiversity can exist in cities (CBD, 2012), which is important for human health and well-being, livelihood opportunities, heat mitigation, and spiritual and cultural values. Developing in a manner that secures this can be extremely difficult to achieve in cities with high levels of endemic biodiversity and pressing social needs, such as housing (e.g., Cape Town, South Africa; O'Farrell *et al.*, 2012). Informality, witnessed through sprawling collections of informal dwellings, is one such key issue and characterises rapid urbanization observed across the Global South. The widespread presence of informality highlights the local realities of poverty, a lack of urban planning and the limited capacity to shape local landscape outcomes. Schneider *et al.* (2012) note the importance of understanding local ecology in determining the role and the impact of urban form both within the city and beyond it. Their work speaks specifically to urban density, water and food relationships, and shows the negative impacts of urban sprawl for biodiversity, productivity, and local ecology. Güneralp *et al.* (2013) note the local impacts of shifting towards meat-based diets within urbanizing areas.

The Cities and Biodiversity Outlook (CBD, 2012) highlights the importance of local knowledge in underpinning urban planning and resource management. Ahrends *et al.* (2010) produced models that demonstrate the role of markets on the degradation of resources within an African city context. Weak governance fails to secure the integrity of local biodiversity resources, allowing continued erosion of public goods. Detailed place-based knowledge and modelled futures around urban projections (Güneralp & Seto, 2013) can be used to inform appropriate local policy development pathways towards sustainable futures. These should include a detailed understanding of infrastructure, incentives and disincentives to promote benign development patterns that simultaneously promote conservation. Contemporary local form in many cities presents opportunities for land managers and decision-makers to improve urban design. Combined with a systemic understanding of nature and its contributions to people, this will allow for effective sustainable planning.

One pivotal policy domain with likely long-term impact on future scenarios relates to the initial choice about local and regional road network structures (Barrington-Leigh & Millard-Ball, 2017; Marshall & Garrick, 2010; Seto *et al.*, 2014). This choice about the configuration and location of road networks is a near-permanent commitment, as compared with other aspects of physical urban form and urban land use. Road networks underlie and constrain all other aspects of urban form, which in turn affect GHG emissions, energy intensity, community activities, and resource use through travel, consumption, extraction and home production patterns (Barrington-Leigh & Millard-Ball, 2015). In addition, high-connectivity, grid-like road networks are conducive to high-density settlement, while low-connectivity road networks are highly resistant to densification. Ensuring all new road networks are highly connected will impact the extent of habitat loss during late phases of urbanization. Prominent ongoing trends in transportation infrastructure present both threat and promise for resource impacts of cities. The electrification of transport promises higher efficiency (lower resource use) but possible rebound (more travel and sprawl). Automation of transport may exacerbate preferences for low-connectivity street-network sprawl, but may also encourage vehicle sharing and free up the large fraction of city space currently used for parking, providing opportunities for improving and reimagining use of urban space.

Regional scenarios and pathways related to nature, urbanization and sustainable development

Regional trends and informants: While urban land-cover area is set to increase, how and where urban areas will expand remains unclear. Work by Seto *et al.* (2012a) on regional influences shows that population growth, international capital flows, informal economies, land use policies, and transportation costs are all important driving factors. These influencing factors vary regionally with variable outcomes, however the regions of greatest anticipated urban expansion are Africa (particularly sub-Saharan), Asia and Latin America. Regional understandings show some shared trends, but also regional variance. Expansion in Africa is likely to emerge in the form of growth in smaller towns, while Asia shows tight coupling between urban expansion and economic shifts, and in Latin America urbanization is characterised by persistent socio-economic disparities (CBD, 2012). In contrast some regions of the Global North are experiencing urban depopulation. In their analysis of national and regional models relating to food production and urban expansion, Nelson *et al.* (2010) found variable impacts on biodiversity and ecosystem services, with various influences and trade-offs at different scales, highlighting the need to consider regional effects in local decision-making and vice versa.

Regional threats to biodiversity

Scenario modelling exploring the relationship between urbanization and protected areas and biodiversity hotspots shows alarming encroachment by cities into these key biodiversity areas, with regional variation. Güneralp and Seto (2013) tracked and modelled urban growth and demonstrate that urban areas are increasing in proximity to protected areas. McDonald *et al.* (2008) reiterate this finding and serve to refine the distances and related impacts between growing cities and adjacent, previously distant, protected areas. The most rapid urban expansion in relation to adjacent protected areas is found in China, while in South America rapid urban expansion also threatens biodiversity hotspots (critical biodiversity areas without formal protection status). Forecasts consistently show overlaps between predicted areas of rapid urban expansion and intact natural habitat and biodiversity, with protected natural assets experiencing increased pressure (McDonald *et al.*, 2008). Also evident here is the variation in regional conservation approaches. Landscape perspectives are required and in this respect we can learn much for scenario modelling from both agriculture and conservation science (Schneider *et al.*, 2012).

Global scenarios and pathways related to nature, urbanization and sustainable development

Linking urban form to sustainable development

Modelled urban scenarios show likely global trends where urban land cover expansion exceeds urban population growth, highlighting the importance at the global scale of considering biodiversity management as an imperative in urban planning. Scenarios by Fragkias *et al.* (2013) suggest that between 2000 and 2030 a 70% increase in urban population will be matched by a startling 200% increase in urban cover, and that 50% – 60% of the total urban cover in 2030 will be built post-2000. McDonald (2008) makes the incontrovertible connection between urban form and per capita resource consumption, demonstrating that urbanization has profound and prolonged implications for oil consumption and climate change, such that new urban design is critically important. Ever-improving understanding of the relationships between existing urban forms and biodiversity can be effectively used to guide future urban design and development for improved sustainability.

Economic flows and telecouplings

It is increasingly recognized that global economic forces play a significant role in determining local urban form and land-cover change. In their footprint analysis, Folke *et al.* (1997) demonstrate how Baltic cities are embedded in a web of connections that stretch far beyond their own immediate environment. These cities from the Global North import and consume from distant regions without a sense of the associated ecological impacts. Folke *et al.* (1997) go on to argue that the economic forces that govern these telecouplings fall beyond the sphere of influence of ordinary citizens. Telecouplings between cities and other areas are very common, as through the provision of water and other resources (Deines *et al.*, 2016; Liu *et al.*, 2015b; Seto *et al.*, 2012b; Yang *et al.*, 2016). The flow of financial capital itself in the form of tax havens is responsible for fuelling much distant environmental degradation, including illegal fishing (Galaz *et al.*, 2018). Understanding telecouplings can help develop appropriate policies that are more equitable and just towards pathways for sustainability (Schröter *et al.*, 2018).

Synthesis and open questions about pathways for cities

The scenarios literature reviewed above coupled with broader literatures on city impacts and ecosystem services suggest the following key elements of sustainable pathways. A central element of sustainable pathways for cities (as in SDG 11) is maintaining nature and its contributions to people within cities and their broader regions (Folke *et al.*, 2009; Russell *et al.*, 2013), and broad access to those contributions, recognizing the multiple and diverse values of city residents (Pascual *et al.*, 2017a). To achieve sustainable development objectives within cities and ultimately develop sustainable cities requires critical engagement across multiple sectors, and a keen understanding of the challenges and action required at local, regional and global scales (Schröter *et al.*, 2018).

At local scales, city-specific thresholds are crucial for retaining species and ecosystem, and for pathways to achieve acceptable levels of urban transformation (CBD, 2012). This is especially difficult in biodiversity-rich areas in developing city contexts (O'Farrell *et al.*, 2012). Linked to this are the needs to strengthen local governance in order to secure public goods, and to enable transdisciplinary planning at local levels such that sectors and departments are bridged and society and businesses are engaged. Such engagements appear fundamental to shaping sustainable urban areas and guiding local-level resource consumption patterns (CBD, 2012).

Facilitating the local realization of global targets for sustainable urban development entails recognizing the emergent differences between and within regions, and the drivers of these (Seto *et al.*, 2012a). Several drivers are key: economic policy and processes, financial underpinnings, infrastructure, investment, and population growth (Seto *et al.*, 2012a). An understanding of how these key drivers impact biodiversity areas (such as protected areas) would be instructive. In particular, cities can work to ensure that biodiversity areas do not become isolated through incompatible surrounding land uses, and that city expansion considers the degree to which encroachment towards these key regional biodiversity sites can be tolerated (Güneralp & Seto, 2013).

Cities play a central role in global pathways because increasing urban land cover affects consumption of resources, including fossil fuels, which in turn propel climate change (Fragkias *et al.*, 2013). Efforts to follow sustainable development pathways within urban areas will thus benefit from a clearer understanding of telecouplings that drive patterns of production, consumption, transportation and disposal, which in turn create and entrench the spatial and social configurations of our cities. This global understanding can then in turn be used to guide local level policy formulation where negative effects are countered and where functioning ecosystems are enhanced alongside their contributions to people (Schröter *et al.*, 2018).

5.3.3 Conclusions from the scenario review

The nexus-based analysis has revealed that no single strategy will yield sufficient transformation to sustainable development and achieve multiple SDGs. All foci suggest that successful pathways entail various measures and instruments applied in concert at local, regional and global scales. All six foci involve trade-offs between sectors and groups, such that compromises are inevitable as conflicting objectives are balanced. However, the six foci also identify potential synergies where some actions have benefits across multiple objectives and for many groups. Here we synthesize five cross-cutting insights from the scenario review, which structure section 5.4 on constituents of pathways to sustainability and are taken up also in the discussion of policy options in chapter 6.

Consumption patterns are a fundamental driver of material extraction, production, and flows, but they too are driven—by worldviews and notions of good quality of life. Addressing aggregate consumption is a central theme in pathways for all foci, but some aspects are more explicit in some than others. For example, although it is aggregate consumption that drives resource extraction and production, research on scenarios and pathways more commonly addressed per capita consumption and waste than population. Similarly, scenario studies quite commonly mentioned the preferences, value systems, and (less often) collective notions of a good quality of life as drivers of consumption, but these aspects were generally not modelled explicitly (See 5.4.1.1 about visions of a good quality of life, and 5.4.1.2 about consumption).

Behaviour change pervades all aspects of transformative change—supply chains and their ecological degradation, but also conservation and restoration. Consumption is effectively a problem of habits and behavioural norms, but so too are changes in practices of production (e.g., agroecological practices in farming), conservation and restoration. All six foci identified such behaviour change as central, but scenario studies varied greatly in the detail with which they envisioned enabling this change. Many studies appealed to a combination of incentives and awareness raising, even though the latter is generally regarded to be a weak enabler of behaviour in relation to infrastructure and consistency with value systems (See 5.4.1.3 about values, agency, and behaviour).

Inequalities and inclusiveness are key underlying problems—good planning helps, but power disparities remain an issue. Across the six foci, many studies highlighted the crucial importance of addressing inequalities and involving people in participatory planning, including the urban poor and Indigenous Peoples and Local Communities. But only a few really addressed the barriers to transformative change that arise from substantial inequities in power, e.g., in the food system, where studies highlighted the difficulties posed by corporate control of seeds, agricultural inputs, and food distribution. The same issues are likely equally important in other foci, e.g., industrial fishers and seafood distributors, but were not discussed explicitly in the studies we found (See 5.4.1.4 about inequalities, and 5.4.1.5 about inclusiveness in planning and conservation).

Larger structural issues underpin all of the above factors—telecouplings, technology, innovation, investment, education and knowledge transmission. Key elements of these structural factors were often largely implicit in pathways analyses, despite their fundamental importance to behaviour change, the dynamics of global social-ecological systems, and the SDGs. The distant effects of local actions caused by telecouplings were central to the cities focus, and implicit in all of the others (e.g., via spatially disjunct supply and demand). Many studies across several foci discussed the potential gains from the spread of beneficial technologies (e.g., the climate mitigation focus), but fewer directly addressed the challenges posed by spread of harmful technologies, or the importance and design of innovation systems that encourage benign technology. Education and knowledge transmission were often addressed in scenarios directly in the form of awareness raising for particular behavioural changes or technology transfer, leaving mostly implicit the crucial roles of education systems for ensuring well-functioning participatory processes (including political ones), and of the transmission of ILK for maintaining local capacities for stewardship (See 5.4.1.6 about telecoupling, 5.4.1.7 about technolgy, innovation and investment, and 5.4.1.8 about education and knowledge transmission).

Sustainability pathway analyses indicate the importance of governance instruments and approaches such as incentives, adaptive management, law and its enforcement. There was near universal acknowledgement of the importance of several governance instruments and approaches, but much more attention to some aspects than others. For example, many studies across all foci appealed to the importance of economic incentives, but generally from a simple behaviourist perspective (as in psychological approaches) without explicit recognition of how incentive programs also effect change by articulating values (as noted in broader social science approaches). Management and governance approaches were commonly discussed as managing several sectors together (integrated management), but much less frequently discussed for early action to address emerging threats (precaution) or managing for resilience and adaptation (these are more explicit in the freshwater realm). Many studies across all foci identified particular environmental regulations, but fewer explicitly considered consistency of monitoring and enforcement although this is often crucial and implicit in scenarios (See 5.4.2.1 about incentives, 5.4.2.2 about integrated management, 5.4.2.3 about precaution, 5.4.2.4 about governing for resilience, and 5.4.2.5 about law and its enforcement).

5.4 KEY CONSTITUENTS OF PATHWAYS TO SUSTAINABILITY: ADDRESSING THE INDIRECT DRIVERS OF CHANGE

The scenario analysis in 5.2 and 5.3 demonstrated that pathways to achieve SDGs and biodiversity targets imply fundamental changes from current trends in all of the world's regions. They are in one sense extremely ambitious, while also necessary and apparently feasible. This scenario analysis also provides key insights about the pathways to realizing the full suite of goals for biodiversity and ecosystem services, but it is not a sufficient source for such insight. Our analysis revealed that some of the issues considered in the literature as central to social-ecological transitions and transformations were largely implicit or even absent in many of the target-seeking and sustainability-oriented scenarios we consulted, such as the role of formal and informal institutions, and other indirect drivers (chapter 2). Following this insight and to characterize the constituents of sustainable pathways comprehensively, the sections below interweave evidence from the scenario analysis (5.3) with evidence from diverse literatures (including those discussed in 5.2.1).

We organize this synthesis of key constituents of pathways to sustainability via eight points of leverage for social-ecological change, and five types of interventions or 'levers' of institutional change for sustainable pathways. These key points of intervention in social-ecological systems can be thought of as 'leverage points' (Abson *et al.*, 2017; Meadows, 2009), while 'levers' are management or governance interventions to effect the transformative change that achieves the collectively agreed-upon objectives for nature and its contributions to people. Note that we use the notion of 'lever' metaphorically, recognizing that global systems—as complex social-ecological systems—cannot be manipulated as neatly as can a boulder with a stick. Rather, we use 'lever'/'leverage point' to illustrate only that these levers and leverage points offer crucial opportunities to engender changes in economies and societies towards achieving shared goals.

Second, levers and leverage points are independently important: the five levers pertain more broadly than the eight leverage points, and other tools may be needed to achieve desired changes in the leverage points. The pathways we identify involve considerable flexibility in *how* to, for instance, promote positive changes in leverage points such as consumption or inequalities. Chapter 6 provides the needed account of policy options for intervention at these specific points. Our five levers, meanwhile, are intended to suggest general and systemic interventions; they are policy tools or governance approaches that are themselves key constituents of social-ecological transitions, to be considered broadly, simultaneously addressing many leverage points and social variables. There are no governance panaceas for social-ecological sustainability (Ostrom, 2007).

Change in any of these levers and leverage points may appear difficult to achieve, but we argue that many are easier to achieve in sets. Change in one aspect may enable change in others (5.4.3 details several nation-scale case studies). For example, changes in laws and policies will enable and underpin changes in management, consumption, and other aspects of behaviour. The reverse is also true: changes in individual and collective behaviours and habits can facilitate changes in attitudes, policies, and laws. Because of these bidirectional influences, there is no one way to order the levers and leverage points. Here we present the leverage points in an order that proceeds clockwise around the outside of the IPBES conceptual framework, spiralling into institutions at the end; levers are ordered from most labile to most lasting and structural (i.e., incentive programs are most easily changed, law hardest) **(Figure 5.7)**.

The analyses of leverage points and levers are organized into three sections. The first section examines each of the identified leverage points as they relate to important dimensions of global social-ecological systems (5.4.1), while the second section discusses levers of change (5.4.2). Each subsection within starts with a statement of the leverage point or lever, followed by any needed *Background*, *Evidence* and a brief discussion of *Possible points of action* (with more detail found in chapter 6). The last section provides examples illustrating leverage points and levers in action, both via national case studies and potential alternative routes that proceed from the bottom up (5.4.3).

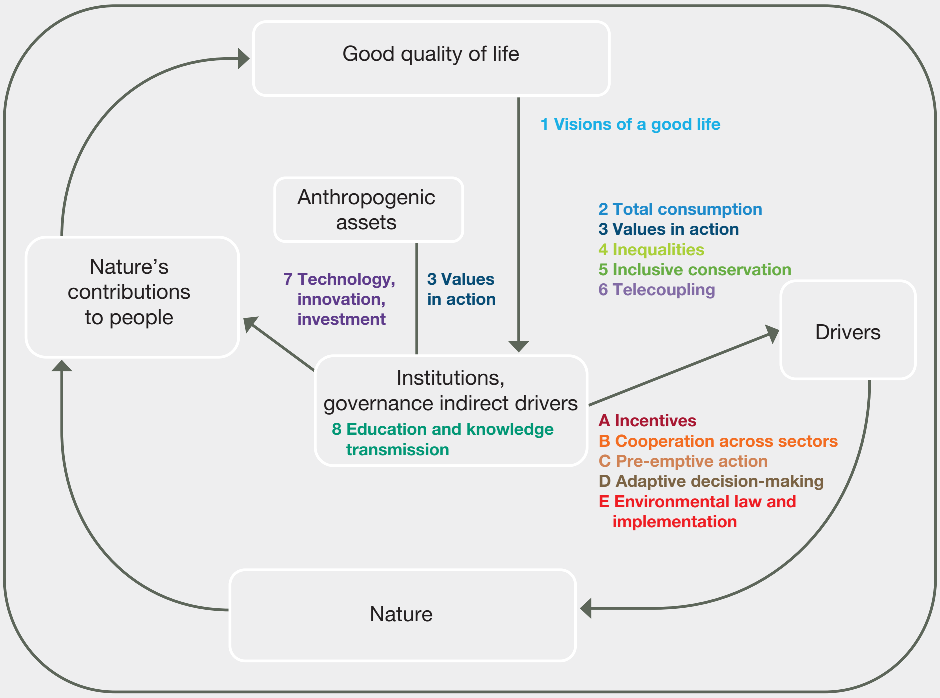

Figure 5 7 **Eight featured leverage points and five levers of transformative change toward sustainable pathways, overlaid on a simplified version of the IPBES Conceptual Framework.**

The leverage points (numbers) and levers (letters) vary in many dimensions, but each has the property that a relatively small change could effect a large change in outcomes for nature and its contributions to people. Change in one leverage point or lever can in many cases also help change others e.g., a change in visions of good quality lives (1) could greatly enable changes in consumption (2). All pertain somewhat to human formal and informal institutions, and in most cases the relationships of these institutions with other elements of the conceptual framework (in particular all five levers could be situated within the Institutions bubble, but they do pertain especially to direct drivers). Figure text for levers and leverage points differs slightly from the subsection headings, for brevity.

5.4.1 Leverage Points for Pathways to Sustainability

5.4.1.1 Visions of a good quality of life and well-being

One of the key drivers of the overexploitation of nature is the currently popular vision that a good life involves happiness associated with material consumption (5.4.1) and success based largely on income and demonstrated purchasing power. However, as communities around the world show, a good quality of life can be achieved with a significantly lower impact on natural resources and ecosystems. Alternative conceptions of a good life can be promoted without paternalism, by valuing and providing the personal, material, and social conditions for a good life with a lower material impact, and leaving to individuals the choice about their actual way of living. In this respect, the renaissance of more relational notions of well-being may be key to achieving nature-based targets. By highlighting the importance of relations to other human and non-human others for a good life we might not only contribute to decoupling consumption and well-being, but also enhance quality of life.

Background

In the academic literature, different terminologies are used to address well-being, happiness, and the good life. In general, 'happiness' refers to self-reported assessments, in which people are asked to articulate via qualitative or quantitative surveys their satisfaction with their own life. 'Quality of life' usually refers to objective indicators (such as the HDI—Human Development Index) that aggregate different data about some essential components of a dignified human life (such as life expectancy, morbidity, education & literacy, inequality). The term 'good life' is more comprehensive and includes the ancient concepts such as "eudaimonia" or "buen vivir", implying in their own way satisfaction with one's own living conditions, aspirations, and meanings, while considering collective and personal principles and virtues (see chapter 1). All these concepts (or philosophies) refer to 'agency', i.e. the ability to decide about how to live according to one's own core values (Sen, 2009). Other than preferences, which are often arbitrary and causal, core values based on deeply held beliefs and guiding principles operate as the basic points of orientation for actions and decisions. Core values can be articulated and justified to others. The concept of a 'good life' is thus linked to forms of justification and claims of justice and goes beyond immediate preferences or feelings of satisfaction.

Approaches to assessing well-being through only objective or subjective measures have generally suffered from criticism. Focusing only on resources underplays the fact that availability of resources does not ensure that they are converted into actual well-being (Nussbaum, 2003). Not only personal differences, but also environmental, institutional, and cultural conditions influence the way in which resources contribute to a good life. Focusing only on self-reported assessments gives insight into what people subjectively consider important for happiness (Layard, 2005), but, if not combined with objective indicators (Happy Planet Index; Bhutan Gross Domestic Happiness Index), it neglects the influence of external factors in determining self-assessment; it might also overlook forms of oppression (self-reported happiness can derive from ignorance of possible alternatives or entitlements, or as a coping strategy under distress). Moreover, people can decide to act according to other motives (altruism, care, etc.) against their personal happiness or advantage, thus following core values in the sense described above.

It is contested how material wealth and growth per capita correlate with (subjective or objective) well-being. While some studies show that, after a certain threshold additional wealth yields diminished happiness returns or decouple from quality of life (Binswanger, 2006; Easterlin *et al.*, 2010; Helliwell *et al.*, 2012; Jackson, 2009; Layard, 2005; Max-Neef, 1995), other recent studies contest these findings (Ortiz-Ospina & Roser, 2017; Veenhoven & Vergunst, 2014). Relative to average or aggregate income, inequality seems to have a larger negative impact on subjective and objective well-being (Oishi & Kesebir, 2015; Wilkinson & Pickett, 2010). It is widely agreed that there is no automatic or obvious correlation between wealth and well-being, but that it depends strongly on institutional, social, and cultural settings that guarantee essential conditions to achieve a good life.

Given the great diversity of conceptions of a good life and well-being, it is important to focus on the *conditions* for leading a good life rather than on the ways in which people actually (choose to) live their lives (Nussbaum, 2000, 2003; Sen, 1999). Such a focus on conditions avoids problems of paternalistic intervention (influencing or forcing people into choosing a specific conception of a good life). A plurality of options for actualization is available once the basic conditions for a good life are guaranteed. Attention can then focus on what process, group, or institution has the legitimate authority to decide what people have reason to value (Deneulin & Shahani, 2009), and to the substantial conditions for participation, including domination structures, actual access conditions, and effective 'power' to be heard and make a difference. Institutions play a key role in framing enabling conditions for a good life. Experiencing life in an environment devoid of dangerous impacts such as those associated with global warming, can be considered a 'metacondition' ('ecological functioning capability'; Holland, 2008; Page, 2007).

Conditions can be *subjective* (preferences), *objective* (material or institutional), and *intersubjective* (social or cultural) (Muraca, 2012). For example, affording shoes can be considered as a subjective condition for happiness (if one loves shoes, collects them, etc.), as an objective condition for being, say, healthy (especially in cold countries), and/or as an intersubjective condition for leading a good life in the face of others in a society, in which wearing shoes is considered a symbol for decency and reliability (Sen, 1987).

When addressing policy interventions about well-being, intersubjective conditions are often neglected, although they play a crucial role especially for change in consumption patterns. Overconsumption is often not only a result of subjective preferences, but also of infrastructural or cultural conditions. For example, if everyone else drives a sports utility vehicle (SUV), driving a small car on the highway is not only a matter of social status but also of personal safety. Having a smartphone up to date is increasingly a necessity for work, but also for access to health services or for social interactions. Such social conditions depend on cultural patterns that influence and are influenced by institutional framing.

Evidence

The orientation towards ways of living based on high material and energy flows is supported by shared values that promote happiness as based on material consumption and success demonstrated mainly via purchasing power and economic status. This model supports what has been termed an 'imperial mode of living' that arguably stabilizes the economies of developed nations while offering a hegemonic orientation to developing countries (Brand & Wissen, 2012).

Since concepts of the good life are influenced by institutional settings and social expectations, social and institutional change can foster alternative conceptions of a good life and guarantee prosperity (Jackson, 2009) with lower material impacts on resources and ecosystems (Røpke, 1999) if combined with the promotion of the fundamental conditions for guaranteeing flourishing (Jackson, 2009; Nussbaum, 2000, 2003). As evidence suggests, competition, inequality, and acceleration of the pace of life—essential components of the idea of a good life based on material consumption—in the long run lead to dissatisfaction (Binswanger, 2006; Easterlin *et al.*, 2010).

A promising path is offered by a widespread renaissance of more relational notions of well-being embodied in various initiatives, social movements, and social groups also in developed countries (see for example the Convivialist Manifesto: http://dialoguesenhumanite.org/sites/dialoguesenhumanite.org/files/meetuppage/103/convivialist-manifesto.pdf; the European Degrowth movement (D'Alisa *et al.*, 2014); or the Transition Town movement (Hopkins, 2008). In Latin America, the promotion of the old concept of "Buen Vivir" also embodies collective deliberations on the conditions of a good life for all, including the rights of nature and ecosystems to flourish. Increasing evidence also supports the conclusion that significant relationships with nonhuman nature are constitutive of a good life for many people both in developed and developing countries (Arias-Arévalo *et al.*, 2018; Chan *et al.*, 2016; Kohler *et al.*, 2018; Muraca, 2016). The use of concepts such as 'relational values' help articulate a more adequate language for why people are willing to invest time and attention to the care of ecosystems (Chan *et al.*, 2016; Muraca, 2016; also see chapter 1).

The notion of a good life that most Indigenous Peoples share is deeply relational: the relation to the land with all its interconnected human and nonhuman inhabitants constitutes their collective self-understanding as community. Livelihoods sovereignty is an essential condition to keep this bond. In Ecuador, the rights of Mother Earth (Pachamama) to preserve its condition of regeneration (a different language for biodiversity and ecosystem services) are considered as inseparable from the conditions for a good life of the people and are protected by the Constitution. The Bolivian Constitution includes the consideration of diversity not only ecologically, but also culturally, affirming the rights of the different and diverse indigenous communities in the conception of a plurinational State. These contributions of nature to notions of a good life may be under threat as access to nature—or key components of nature—are lost (Chan & Satterfield, 2016; Garibaldi & Turner, 2004; Kohler *et al.*, 2018; Louv, 2008; Miller, 2005; Nabhan & St Antoine, 1993).

Possible points of action

Governments and other institutions are responsible for enabling subjective, objective, and intersubjective conditions for a good life. Successful policies would generally target the different drivers that affect the desirability and burden of alternative ways of being: socioeconomic (such as competition-driven investment in innovations and the need for new market opportunities), structural (dominant understandings that equate economic growth with well-being), and socio-psychological and cultural (including the social relations in which humans are embedded) (Røpke, 1999).

Promoting alternative conceptions of a good life does not require paternalistic interventions: if the material, social, and personal conditions for a good life are sustained in ways that do not require a high material and energy flow, individuals have the freedom to choose alternative modes of living without significant impairing their quality of life. In this case, sufficiency would not only be an individual choice of voluntary simplicity, but also the legitimate entitlement to a sufficient lifestyle, i.e., the right to have less, to have a slower pace of life, to escape the escalating competition for success and enhancement ('hedonic treadmill'; Binswanger, 2006), without suffering a significant lack in the conditions for a meaningful and dignified life (Winterfeld, 2007). For example, if access to essential services (such as communicating with one's physician or buying a bus ticket) requires specific up-to-date technology, choosing not to use them heavily impacts access to health and mobility. Institutional framing can make the choice of a sufficient and low-impact lifestyle achievable for a large majority of the population, by eliminating burdens or negative incentives.

Improving affordable, spatially inclusive and comprehensive public transport infrastructure would expand fundamental entitlements to mobility, enabling people to embody more collective notions of a good life without substantial compromise to security, comfort and efficiency.

Regulation of planned obsolescence for technological products would shift innovation towards ecological design and long-lasting, modular products, thus increasing the freedom of choice of consumers while improving the social and environmental conditions under which electronic devices are produced. It would also in the long run affect the cultural understanding of innovation and originality while significantly reducing environmental impacts (e.g., through rare earths mining).

Expectations of increasing speed in social interactions often correlate with increasing impact on nature due to associated infrastructural needs. Policies and programs that counteract acceleration tendencies and promote spaces for solidarity, care, creativity, and democratic participation might enable the achievement of essential features of a good life and expand freedoms. Technological innovation can significantly contribute to reframing the conditions of acceptability of social behaviours as well (e.g., the "do not disturb while driving" feature on recent smartphones might reduce the expectation of immediate response to messages).

Such interventions would foster a shift—in the long run—from the role of consumers to that of users (Lebel & Lorek, 2008) without significantly impairing the capabilities of people to achieve valuable doings and beings. Supporting alternative modes of production based on peer-to-peer processes would increase local resilience, make technologies accessible and decentralized, and promote the autonomy and self-determination of local communities (Kostakis & Bauwens, 2014).

Ultimately, a fundamental condition for a good life is the possibility of deliberation and negotiation within a society. Participatory parity (Fraser, 2007) is key. This entails different social groups being able to speak in their own terms and language about their understanding of a good life and enabled to participate in the framing of its conditions (Fraser, 2007).

5.4.1.2 Aggregate consumption (a function of population, per capita consumption and waste)

Beyond improved efficiencies and enhanced production, all pathways to reducing biodiversity loss entail reducing or reversing the growth of aggregate consumption, as a function of population size and per capita consumption and waste. Per capita consumption tends to rise as income rises, putting further pressure on biodiversity. Upward trends in population growth have and will lead to further biodiversity loss and increasing numbers of threatened species. The need for transformative changes in consumption patterns is particularly pertinent for wealthier nations and people.

Background

Across 114 nations, the number of threatened species in the average nation is expected to increase by 14% by 2050 (McKee *et al.*, 2004); and increased efficiency in food production is unlikely to compensate sufficiently for the negative impact of human population growth and increasing per capita consumption on biodiversity (Crist *et al.*, 2017). Expected changes in population and income between 2010 and 2050 suggest that the environmental effects of the food system, as one example, could increase by 50–90% without substantial technological changes and dedicated mitigation (Springmann *et al.*, 2018a). Globally, decreases in consumption are thus critical, recognizing that there are significant inequalities within and between countries in consumption related to food, energy, water, and other natural resources (O'Brien & Leichenko, 2010).

Aggregate consumption is a function of population size *and* per capita consumption. An example of these effects at a fine scale is that households with fewer members tend to have higher per capita consumption, with consequences for biodiversity, especially in biodiversity hotspots (Liu *et al.*, 2003). Cities are more efficient resource-users per capita than sparsely populated areas due to economies of scale, in particular with infrastructure (EEA, 2015). On the other hand, urbanization has also been found to increase consumption at the household scale. Specifically, the ecological footprints (an index of major consumption categories at the household level; see chapters 2 and 3) of nineteen coastal cities across the Mediterranean reveals that per capita footprints are larger on average than parallel rural populations. The main drivers were found to be food consumption, transportation and consumption of manufactured goods (Baabou *et al.*, 2017). In general, the co-benefits of urban systems as both source and solution of environmental effects are not well studied.

Evidence

Aggregate consumption (the product of population size and per capita consumption and waste) is undisputably a key driver of environmental degradation (Dietz *et al.*, 2007; Ehrlich & Pringle, 2008; Rosa *et al.*, 2004). As one prime example, food consumption drives the agricultural sector (which covers 38% of Earth's surface), and is as a primary source of environmental degradation and GHG emissions (both drivers of biodiversity loss). Seventy-five per cent of that agricultural land is used for livestock production (Foley *et al.*, 2011). In particular, demand for animal source foods has more than tripled over the past 50 years due to population growth and dietary change (Delgado, 2003; Thornton, 2010). Livestock production (grazing and feedstock) is the single largest driver of habitat loss, a pattern increasing in developing tropical countries where the majority of biological diversity resides. The projected land base required by 2050 to support livestock production in several megadiverse countries exceeds 30–50% of their current agricultural areas (Machovina *et al.*, 2015). Some reduction in biodiversity loss can be offset through technological gains such as yield gains in agriculture due to intensification (Wirsenius *et al.*, 2010), but these do not yet keep pace with simultaneous growth in population and income (West *et al.*, 2014).

Changes in consumption patterns are among the most prominent elements in storylines used in scenarios that lead to achieving SDGs, including all three elements (population size, per capita consumption, and waste). The core global studies (Roads to Rio+20, Pathways to the 1.5ºC target, and Bending the Curve—5.3.1.2) all assumed relatively low stabilized global population sizes and various scenarios of reduced overconsumption and waste. More specifically, Stehfest *et al.* (2009) showed that four scenarios of dietary variants, all involving reduced meat consumption yielded diminished land-use change (and associated, non-modelled, benefits for BES) and reduced emissions and energy demand. Meanwhile, energy scenarios suggest that focusing on the energy use of sectors, not people, would lead to substantial reduction in energy demand (see McCollum *et al.*, 2012's energy efficient pathway).

These patterns in scenarios contain some important complexities but lack others. One key missing nuance in large-scale scenarios is the minimal representation of rebound effects (Jevons paradox), by which consumption often tends to increase in response to gains in efficiency in production or resource intensity, erasing some or all of the gains (e.g., LED lighting may be more efficient but enable much more lighting in total; more abundant energy may encourage greater consumption) (Alcott, 2005). Accounting for these rebound effects would make the case even clearer that ***increased production and efficiency are not sufficient, without also addressing consumption itself***. In terms of food consumption, modelled patterns often somewhat underrepresent variation within agricultural systems, and the important role dairy and foods of animal original play in childhood, maternal (during pregnancy) and elderly nutrition (FAO, 2016)(). For instance, few scenarios account for feedbacks between changing availability of protein affects local hunting or fishing (Brashares *et al.*, 2004), where wild-based and so small-scale economies, such as bushmeat provisioning, have also been identified as an important driver of biodiversity loss (Fa *et al.*, 2005; Nasi *et al.*, 2008). Terrestrial wildlife, especially ungulates, are a primary source of meat for millions globally. Wild meats are however an important source of childhood nutrition, without which an estimated 29% increase in children suffering from anemia would occur, leading to health, cognitive and physical deficits in poor households (Golden *et al.*, 2011). Virtually all models do include some level of meat and fish derived proteins. Furthermore, all models related to the role of dietary changes recognize that dietary changes, such as lowering animal protein consumption do not apply to undernourished and vulnerable populations. The general point is that lowering consumption of animal protein is important; and that variation aside, even the lowest impact of animal protein production typically exceed the impact of plant-based options (Clark & Tilman, 2017; Poore & Nemecek, 2018).

Waste is equally key. A large amount of food, including animal products, is wasted worldwide, e.g., roughly 30% in the U.S. when accounting for production through household waste (Nellemann, 2009). Wasting 1 kg of feedlot-raised boneless beef is estimated to have ~24 times the effect on available calories as wasting 1 kg of wheat (~98,000 kcal versus ~4000 kcal) due to the inefficiencies of caloric and protein conversion from plant to animal biomass (West *et al.*, 2014). Waste varies greatly between countries: food loss in India for vegetables and pork is <3 kcal per person day–1, versus ~290 kcal per person day–1 for beef in the United States. Approximately 7 to 8 times more land is required to support this waste in the United States than in India (Machovina *et al.*, 2015). Overall, because waste in the production cycle is so variable, even for the same food types and classes, producer-level monitoring and mitigation will be key to achieving more sustainable pathways (Poore & Nemecek, 2018).

Overproduction (when not discarded to prop up prices) and associated marketing can also drive consumption: if subsidies or other forces yield an oversupply of a commodity or good, this will lower prices, and consumption of those goods and their embodied resources will tend to rise. Producers can boost these effects strongly through advertising, which can yield self-reinforcing dynamics in consumer culture (Berger, 2015; Isenberg, 2017; Philibert, 1989).

Possible points of action

It is estimated that countering these driving forces would require incentives for increases in the efficiency of resource use of about 2% per year (Dietz *et al.*, 2007), and no single measure or action will be sufficient. Intensification will offset some effects of consumption in the agricultural sector, but much gain would accrue via reduction in meat consumption through demand reduction and dietary shifts (Foley *et al.*, 2011). As with all efficiencies, some rebound effects are to be expected and addressed (e.g., increased demand that follows initial gain through efficiency) (Alcott *et al.*, 2012).

An estimated 1.3 to 3.6 billion fewer people could be fed if diets shifted to lessen reliance on animal products, particularly resource-demanding ones (while maintaining the relative contribution of grazing systems) (Davis & D'Odorico, 2015). Some analyses suggest that targeting Western high-income and middle-income countries would yield the largest potential gain and focus for the environmental (and health) benefits of dietary changes at a per capita level (Springmann *et al.*, 2014). Improvements in consumption patterns can likely be achieved by reducing subsidies for animal-based products, increasing those for plant-based foods, and replacing ecologically inefficient ruminants (e.g., cattle, goats, sheep) (Machovina *et al.*, 2015). Research and development of plant-based meat substitutes is also a growing phenomena and potential solution (Elzerman *et al.*, 2013; see also Poore & Nemecek, 2018; Springmann *et al.*, 2014, 2018b).

Significant targeting of waste is also an important policy target; well tested approaches include regulations for Extended Producer Responsibility whereby producers manage the waste generated by their products (OECD, 2016).

Given the central role of advertising and marketing in boosting production, policies might seek to rein in the reach of advertising, particularly to children and for resource-intensive products. Lastly, broader changes in consumption could be triggered by promoting alternative models of economic growth (e.g., as proposed by the World Business Council for Sustainable Development, WBCSD, 2010), which may also offer higher likelihood of achieving SDGs 2, 6, 15.

5.4.1.3 Latent values of responsibility and social norms for sustainability

Sustainable trajectories are greatly enabled by context-specific policies and social initiatives that foster social norms and facilitate sustainable behaviours. An important step toward this goal would be to unleash latent capabilities and relational values of responsibility (including virtues and principles; 5.4.1.1). Such values may often be strongly held in relevant populations, but not manifest in large-scale action due to a lack of enabling conditions, including infrastructure and institutional arrangements. Because communities, the values they hold, and barriers to enacting values are all diverse and multifaceted, social norm-shifts and widespread action are most likely to stem from locally tailored programs, policies and investments.

Evidence

There is strong evidence that many populations already express values consistent with sustainability, such as pro-environmental values (e.g., Dunlap & York, 2008) and relational values (Klain *et al.*, 2017). These values manifest differently in different places (Chan *et al.*, 2016). For example, Haidt & Graham (2007) document a striking difference in moral foundations between progressive and conservative voters in the USA, and the World Values Survey reveals two major axes of difference (traditional vs. secular-relational values and survival vs. self-expression values) (World Values Survey, 2016). In both of these frameworks, values on either end of these spectra could support sustainability.

Ample evidence supports that the expression of such values is currently impeded by insufficient infrastructure and social structures (Shove, 2010). This 'social practice' strand of research demonstrates the need for explanations of collective action (e.g., issues involving greenhouse gas emissions) to go beyond the aggregate of individual people operating independently. This research suggests that the focus on individual attitudes, behaviours, and personal choice needs to be expanded to include systemic considerations, such as the role that governments play in "structuring options and possibilities" (Shove, 2010). As one important possibility, sometimes norms can be promoted in new contexts by foregrounding existing widely held norms and values, and their applicability to the issue at hand via a process called 'normative reframing' (Raymond *et al.*, 2013). Thus, notions of justice or fairness can be applied in new environmental contexts, either through normative reframing or even the creation of new norms in 'normative innovation' (Raymond *et al.*, 2013).

Extensive work on barriers to pro-environmental behaviour, which originates from an individual-focused paradigm, also often discusses two main realms of barriers: personal and collective. This work provides evidence that individual-level factors (e.g., disposition) play a role in behaviour, and it also confirms the importance of factors external to the individual (Darnton & Horne, 2013; Kollmuss & Agyeman, 2002). In short, though individual motivation is important, the problem is sometimes or often not that individuals lack motivation for action (e.g., on climate change), but rather that current infrastructure, habits, and norms are outdated and insufficient to express values already present. An example from the United States relates to personal transportation, many people report wanting a lower carbon alternative to personal vehicle travel, but their communities are designed in such a way that make other options prohibitively inconvenient and/or unappealing (Biggar & Ardoin, 2017b, 2017a; Shove & Walker, 2010).

Related to the point above, but stemming from a parallel literature, extensive behavioural economics and psychological research suggests that human decisions are heavily impacted by context and structures. There is strong evidence from a range of studies and a larger body of social sciences literature that replacement or evolution of infrastructure and social structures could nudge change in individual behaviour and also contribute to the formation of pro-sustainability habits and norms (Pallak *et al.*, 1980; Thaler & Sunstein, 2008). A fundamental idea underlying this philosophy, which has been called "liberal paternalism" because it allows free choice (liberal) but guides people (paternalistic), is that people often want to act differently than they do, and would often appreciate a "nudge" to help them act in accordance with their deeper values. One specific example would be that people wanting to purchase sustainable seafood have benefited from a green-yellow-red signaling system, especially when those signals are displayed beside the products in stores and restaurants. A more general example would be that people wanting to donate more to charity generally give more with automatic payment plans.

Additional evidence suggests that despite the responsiveness of human behaviour to existing contexts, moral belief and conviction already do transcend purely selfish action and/or more mechanical responses (e.g., of the type described by moral psychology or behavioural economics) (Damon & Colby, 2015). Learning can help people develop these responses based on morals and conviction, especially when that learning employs dialogue, reflection, reasoned argumentation, and deliberation (all of which practices are increasingly recommended by education scholars; see 5.4.1.8). A cornerstone of much moral philosophy is the idea that people can engage with complex situations and, through conscious deliberation and moral judgement, change behaviours and lifestyles. Acknowledging the aforementioned substantial impact of sometimes minor situational and contextual variables, it is helpful to also consider research into human moral choice, and how morality and moral decisions come about. Much research in this realm highlights the importance of intentional effort, deliberative discussion and thought (including in education), not as an alternative to 'nudge' approaches but as a complement (John *et al.*, 2009; Reed *et al.*, 2010).

Fifth, the burgeoning science of norms offers important insight into how to change behaviour. The science of norms considers the interplay of proximate contextual factors (e.g., what people around us are doing) and more deeply rooted social, collective understandings of "how things should be." Norm-based interventions are some of the most prevalent and effective means of changing behaviour (Miller & Prentice, 2016). As one example, household use of electricity decreases following messages about neighbors who use less electricity (the addition of a message conveying social approval/disapproval further strengthens the change; Schultz *et al.*, 2007). Norms interventions, particularly related to environmental issues, are less common in developing countries; an example from the health field is that decreases in female genital mutilation followed interventions that attended to social norms along with other aspects of local context (Cislaghi & Heise, 2018). Research on the dynamics of norms (i.e., how norms change) focuses on the need to change expectations, both about what others will do and what others think people should do (Wegs *et al.*, 2016). Legislation can affect these changes under specific conditions (e.g., when policies are not too far from aligning with existing social norms) (Bicchieri & Mercier, 2014). For most cases, however, interpersonal interaction is central to changing norms. Discussion can encourage prosocial behaviour by signalling and emphasizing desirable behaviours and norms (Balliet, 2009; Sally, 1995). Discussions also help people understand why others feel as they do and allow people to grapple with disagreement. In some situations, for instance those in which people need to be convinced, argumentation may be required (Bicchieri & Mercier, 2014). Work from a variety of fields confirms the importance of interpersonal interaction and discussion; one study, for instance, found time spent with neighbors to be strongly correlated to "environmental lifestyle" and "willingness to sacrifice", emphasizing the importance of non-kin social relationships and interactions (Macias & Williams, 2014).

For IPLCs, values of all kinds (e.g., instrumental, intrinsic, relational) are deeply intertwined with cultural and environmental contexts, and value systems are often represented in and reinforced by language. The loss of language may be associated with value deterioration or change. Many (if not all) languages codify values related to the ability to coexist with surrounding environments for hundreds or thousands of years (Davis, 2009; Maffi, 2001). These sustainability-related values may be particularly common in Indigenous and other long-standing local communities, with their strong traditional beliefs, laws, customs, culture, and affections towards nature (e.g., sacred trees, sacred animals, totems) (e.g., McGregor, 1996; Turner, 2005). As such, the loss of languages is potentially a major problem for value diversity and authenticity. In many regions, community values that support sustainable trajectories using indigenous knowledge are at risk of extinction, which results in the loss of biodiversity (Unasho, 2013). Loh and Harmon (2014) note that one in four of the world's 7000 languages are at current threat of extinction, confirming a simultaneous decline in linguistic diversity and biodiversity – approximately 30% since 1970. Extinction statistics tell the story: 21% of all mammals, 13% of birds, 15% of reptiles, 30% of amphibians and 400 languages have gone extinct (Loh & Harmon, 2014). In this sense, the value of the knowledge-practice-belief complex of Indigenous Peoples relating to conservation of biodiversity are central to the sustainable management of ecosystems and biodiversity.

Possible points of action

A particular challenge faces people participating in global supply chains (e.g., through their purchasing of goods and services), because although there might be broad and strong agreement with the notion that we humans have a responsibility to account for our impacts on the environment (Klain *et al.*, 2017), there are a dearth of options for people to do so easily, enjoyably, and affordably (Chan *et al.*, 2017b). That is, the primary option available to consumers is the purchase of certified products (e.g., Marine Stewardship Council seafood, forest-stewardship council wood products, organic food), but these are inevitably costly, limited, and complex (few consumers can keep track of and come to trust more than a few of the plethora of competing labels). Because the costliness stems partly from inefficiencies in these niche supply chains, there is potential to enable widespread action in accordance with values of environmental responsibility via credible non-tradeable offsets that enable organizations and individuals to mitigate their impacts on nature (Chan *et al.*, 2017a). A legitimate and trusted system of such offsets does not yet exist, but there are important developments and novel efforts (e.g., the Natural Capital Project's Offset Portfolio Analyzer & Locator, Forest Trends' Business & Biodiversity Offsets Programme, CoSphere).

Offsets have a potentially important role to play because they could enable people and organizations to enact values of environmental responsibility that are currently suppressed by disabling conditions, but which could potentially yield new social norms. However, to achieve that, it will be crucial that offsets avoid the problems and associated negative reputation that has plagued carbon offsetting, such that offsets convey the real and socially legitimate mitigation of diverse impacts on nature and its contributions to people (Chan *et al.*, 2017a).

5.4.1.4 Inequalities

Inequality often reflects excessive use of resources or power by one or more sectors of society at the expense of others. As societies develop and aim to 'catch up' in economic growth, inequality often emerges through control and appropriation of unequal shares of finite resources with implications for both creating unjust social conditions and loss of nature and its contributions. Therefore, addressing societal inequities is not only important for its own sake and for moral reasons, but as leverage to facilitate achievement of biodiversity goals.

Background

The world is currently experiencing increasing levels of inequality in many sectors of society, including between, within countries and across countries (Stiglitz, 2013). Although assessments of inequality often focus on income, there are many dimensions of societal inequalities such as distributive, recognition, procedural and contextual inequities (Leach *et al.*, 2018). Distributive equity refers to the distribution of costs and benefits, and questions of who gains and who loses. This is very applicable for example to the climate discussion where questions are raised about who bears the responsibility for or burdens of climate impacts (Collins *et al.*, 2016; Dennig *et al.*, 2015). This may also include discussion about unequal access to health across and within countries (Costello & White, 2001; Joshi *et al.*, 2008) or inequality in access to energy (Lawrence *et al.*, 2013; Pachauri *et al.*, 2013) and inequalities in income distribution (Alvaredo *et al.*, 2018; Piketty & Saez, 2014; Ravallion, 2014). Procedural equity refers to access and participation in decision-making processes and applies to discussion about gender inequality and representation in governance structures, education, and other spheres of society (McKinney & Fulkerson, 2015). Recognition equity refers to accounting for stakeholders' knowledge, norms and values, and this is the main driving force behind IPBES and other organisations' calls for including indigenous and local knowledges, expanding the values base and opening up to multiple forms of evidence (Díaz *et al.*, 2015; Nagendra, 2018; Pascual *et al.*, 2017a; Tengö *et al.*, 2017). Finally, contextual equity refers to deep rooted social conditions, such as gender, social structure, discrimination and historical legacies that help to explain why inequality is perpetuated and reproduced over time (Martin *et al.*, 2016; McDermott *et al.*, 2013). All these different dimensions of inequities and inequalities can apply variously to gender equity, equity between specific groups, or between vulnerable groups and between different segments of society (Bock, 2015; Daw *et al.*, 2015; Keane *et al.*, 2016; Terry, 2009).

Evidence

Global inequalities, between and within countries, include inequities in income and wealth, inequities in access to resources and other benefits, as well as inequities in who bears the brunt of global change.

Globally, income inequality is increasing while biodiversity loss continues apace (Butchart *et al.*, 2010; Dabla-Norris *et al.*, 2015). Although the mechanisms of how income inequality affects biodiversity loss are not yet articulated comprehensively, there is some indication that income inequality is positively correlated with biodiversity loss. Inequality has been associated with an increasing number of social and environmental problems (Islam, 2015; Jorgenson *et al.*, 2017; Wilkinson & Pickett, 2010). Several studies suggest some initial hypotheses for the observed negative coarse-scale correlations between biodiversity and inequality (Holland *et al.*, 2009; Mikkelson *et al.*, 2007; Mikkelson, 2013). Here income inequality, measured using the Gini index, is correlated positively with threatened species, suggesting that inequality may exacerbate biodiversity loss. It also appears that a psychological acceptance of inequality (as measured by the social domination orientation) is negatively correlated with a variety of environmental actions and behaviours, and that this negative relationship is stronger in nations characterized by societal inequality (Milfont *et al.*, 2017).

More broadly however, inequality is seen as resulting from broader structural issues. In this way, unequal access to incomes, resources, consumption and other forms of inequality are symptoms of larger structural configurations related to power asymmetries and political influence (Cushing *et al.*, 2015; Pieterse, 2002). Some of explanations of this assertion include the existence of phenomenon such as 'ecologically unequal exchange', which is a structural mechanism allowing for more developed countries to partially externalize their consumption-based environmental impacts to lesser developed countries (see chapter 2.1; Jorgenson *et al.*, 2009). While there are some nuances to this suggestion (Moran *et al.*, 2013), there is evidence showing unequal consumption patterns between developed and developing countries (Wilting *et al.*, 2017), and 'trade of biodiversity' from developing countries to developed countries (Lenzen *et al.*, 2012). For example, there is evidence suggesting inequalities in access to health (Costello & White, 2001; Joshi *et al.*, 2008), energy access (Lawrence *et al.*, 2013; Pachauri *et al.*, 2013), climate change and other environmental burdens and responsibility (Collins *et al.*, 2016; Dennig *et al.*, 2015), income distribution (Alvaredo *et al.*, 2018; Piketty & Saez, 2014; Ravallion, 2014), between countries, individuals, genders and other socially differentiable segments of society (Aguiar & Bils, 2015; Bebbington, 2013; Chaudhary *et al.*, 2018; Lau *et al.*, 2018; Piketty & Saez, 2014).

Possible points of action

There are increasing numbers of suggestions and solutions for addressing inequality in society. For example, the concept of 'common but differentiated responsibility' has taken root in multinational agreements, is now a principle within the United Nations Framework Convention on Climate Change (UNFCCC). It acknowledges the different capabilities and differing responsibilities of individual countries in addressing climate change (Rajamani, 2000; Stone, 2004). Given different countries' historically different responsibilities and benefits in use of and access to resources, this principle could be applied more broadly to other spheres of biodiversity management.

Within nations, there are other solutions to inequality such as United Nations Development Programme's Inclusive Growth (UNDP, 2017). Others still advocate for universal provision of services including universal health care, universal education, basic social services, and regressive taxation. One of these universal provisions that is gaining traction is universal basic income (Lowrey, 2018).

5.4.1.5 Human rights, conservation and Indigenous Peoples

Sustainable trajectories that achieve biodiversity and Sustainable Development Goals need to maintain or enhance ecosystem services on which livelihoods depend as concerns Indigenous Peoples and land-based (and often poor) people living in or adjacent to all classes of protected areas. Achieving large-scale engagement of Indigenous Peoples and Local Communities (IPLCs) in protected areas governance entails (a) recognition of and compensation for historical wrongs and transgressions of rights in conservation contexts; (b) IPLC-led planning, decision-making and consent (which is significant and robust); and (c) connection of local efforts with larger connected landscapes/seascapes to enable the continued benign use of ecosystem services in broader landscapes and seascapes. Human rights are linked to but not inclusive of the rights of nature across these considerations.

Evidence

Some conservation efforts have led to Indigenous Peoples and Local Communities being displaced from traditional territories and deprived of access to resources essential to their livelihood (Agrawal & Redford, 2009; West & Brockington, 2006; see also chapters 3 and 6). This was true across many colonial administrations wherein reserves were often created as hunting reserves or settler communities (Griffiths & Robin, 1997; Neumann, 1998). These reserves impinged upon forest and land-dependent communities (Duffy *et al.*, 2016). There are also reports of similar patterns of restrictions and conflicts with contemporary pastoralists (Holmern *et al.*, 2007) and swidden agriculturalists (Harper, 2002). As conservation efforts have escalated in the contemporary period, this pattern has continued, with some exceptions (Davies *et al.*, 2013). International organizations in the last two decades have come to recognize that the involvement of local people is an essential prerequisite of any attempt to achieve better conservation and natural resource management (Kakabadse, 1993; McNeely, 1995). However, there have been ongoing reports of violent and militarized conservation actions including shoot-to-kill orders issued for poachers (Lunstrum, 2014). Recent examples come from the USA, Cambodia and southern African countries (Ramutsindela, 2016), including cases where relocation has failed and violence has escalated as a partial consequence (Hübschle, 2016).

In many countries, both in Global North and South, the processes of allocating land rights are still a work in progress. People with legitimate and historical rights to territorial use and jurisdiction have often had difficulty gaining recognition of these rights in processes of land allocation. Misidentifying people as stakeholders rather than rights-holders has often enabled human rights abuses by lessening the obligations of duty bearers (those responsible to protect and enable viable conditions such that human rights are ensured) (Alcorn & Royo, 2007). Failure to recognize the presence and role of historical wrongs has often deepened or exacerbated tensions about or the creation of just forms of conservation (Chan & Satterfield, 2013). This has included histories of displacement often linked to 'fortress conservation' (Büscher, 2016), forced relocation and loss of livelihoods (Brockington & Igoe, 2006), colonial legacies, transgression of treaty rights, and failed restitution for historical losses (Colchester, 2004). The designation of protected areas without meaningful involvement of those most affected (Hockings *et al.*, 2006) has been widespread, so much so that some populations are not aware that they are living within a designated protected area and that conditions of use have thus changed (Sundberg, 2006).

Pressure from national and international organizations related to human rights and to conservation has placed pressure on policymakers in countries with rich biodiversity, sometimes with undesirable effects. Even attempts to achieve conservation through community-based management have not always fully addressed the fundamental rights of local people, even in better designed systems such as those known as community-based conservation (Berkes, 2004; Campbell & Vainio-Mattila, 2003). Cernea and Soltau (2006) have documented cases where conservation has deepened poverty and food insecurity as a result of restrictions imposed on resource use, most acutely in cases of forced relocation or involuntary resettlements. Sachs *et al.* (2009) have documented cases where a disproportionate conservation burden has been placed on already poor and marginal communities thereby increasing transitions into more severe forms of poverty.

The loss or degradation of social status has also accompanied conservation activities, often due to the relocation of peoples to hostile host communities (Martin, 2003) or the stigmatizion of some peoples because their land-use practices are deemed destructive by conservation agents (Bocarejo & Ojeda, 2016). Compensation for losses directly attributable to conservation (e.g., due to loss of lands, or loss of resources or income as the result of human-wildlife conflicts) have often been insufficient (Cernea & Schmidt-Soltau, 2006) or have failed to recognize losses most meaningful to impacted communities (Witter & Satterfield, 2014). Communities have often waited far too long in far too compromising circumstances for promised relocation packages when being moved to improve the status of parks and protected areas (Hübschle, 2016). Lastly, when conservation efforts have been poorly executed due to problems of governance, corruption, or in areas with histories of war and armed conflict, violent and militarized conservation has often ensued and harmed human and nonhuman communities (Smith *et al.*, 2015).

Given the vast lands over which IPLCs exercise traditional rights, recognizing land rights and partnering with Indigenous Peoples could greatly benefit conservation efforts (Garnett *et al.*, 2018). According to Garnett et al. (2018), Indigenous Peoples either traditionally own, manage, use or occupy at least a quarter of the global land area, constituting approximately 40% of land that is currently protected or ecologically intact. IPLCs frequently have a rich set of relational values regarding nature and their interactions with it, and some of these are consistent with conservation, although often not as it has been practiced historically (through exclusion) (Chan *et al.*, 2016; Pascual *et al.*, 2017a). Involving IPLCs justly and appropriately in conservation could help them manage other pressures, such as resource extraction, in a way that meets both local and global needs.

Possible points of action

Recent innovation among conservation organizations has seen investments in engaging local communities in exploring future scenarios to achieve conservation and development, thus involving communities at an early stage of conservation and sustainable development programs (Boedhihartono, 2017; Clarke, 1990; Curran *et al.*, 2009; chapter 6).

Needs remain, however, for measures to directly and indirectly address enduring negative consequences of conservation for local and Indigenous Peoples. Improved forms of community-based conservation might ensure that the rights of nature do not supersede human rights (Hockings *et al.*, 2006). For instance, conservancies established in southern Africa have enabled local decision-making to be sustained across decades (Boudreaux & Nelson, 2011; Tallis *et al.*, 2008). Many countries are beginning to return land and forests to local communities and indigenous groups. Notable successes have been achieved in the last decade, and wider adoption of such programs for forests and biodiversity conservation could address the issues raised here (Adams, 2001; Boedhihartono, 2017; Sayer *et al.*, 2017).

Adaptive management (5.4.2.4) is viable when people are well integrated into the social-ecological system being conserved, and distribution of economic and social benefits contribute to improve the lives of IPLCs (Berkes, 2004; Infield & Namara, 2001). There are examples of successful action drawing on traditional ecological knowledge and practice, which have been combined with western concepts of conservation to produce multi-disciplinary management outcomes (Gadgil *et al.*, 2000; Huntington, 2000).

Enabling local definitions and targets for nature's contributions to people is also key, especially those that go beyond market measures and enhance well-being (Sandifer *et al.*, 2015). Working with locally-defined compensation and resettlement planning can help improve or restore livelihoods and development opportunities (Bennett *et al.*, 2017; Vanclay, 2017). Compensation for crop losses can also improve support for conservation initiatives and is being widely used, though challenges remain (Karanth & Kudalkar, 2017; Nyhus *et al.*, 2005).

In the rare instances where relocation appears necessary, fairness might dictate the suspension of processes if they cannot be realized well and fairly in an appropriate time frame (Hübschle, 2016). Strong stances against militarized and armed conservation will help restore deeply eroded people-park relations and 'de-criminalize' livelihoods (Duffy *et al.*, 2015).

Schemes such as payments for ecosystem services (PES) are most likely to succeed in conditions where livelihoods are already relatively secure, and payments are supplemental and not a replacement for income or food security (Pascual *et al.*, 2014).

The social complexities of landscapes can be integrated when designing compensation schemes for conservation at community levels (Wunder *et al.*, 2008). It is inevitable that trade-offs will occur between biodiversity and ecosystem service goals (chapter 2.3), but these trade-offs can be made fairly if addressed explicitly and democratically (Borrini-Feyerabend *et al.*, 2013).

Last, Indigenous Peoples and Local Communities can be integrated, along with other actors, in landscape-level governance through the recognition of both ancient practices and innovative mechanisms. The relationship between human activities and the environment also creates unique ecological, socioeconomic, and cultural patterns, and governs the distribution and abundance of local species, which are often described as cultural landscapes in western society (Farina, 2000; Plieninger & Bieling, 2012). Exemplar practices exist in other parts of the world that represent harmonious interactions between humans and the nature such as Satoyama and Satoumi of Japan, Pekarangan (homegarden) of Indonesia, Chitemene of Zambia, Malawi, and Mozambique, and are now collectively described as 'Social-Ecological Production Landscapes and Seascapes (SEPLS)' (Gu & Subramanian, 2014; Takeuchi, 2010). Similarly, the framework and designation of the Globally Important Agricultural Heritage Systems (GIAHS) by FAO since 2002 and the International Partnership for the Satoyama Initiative (IPSI) since 2010 (Box 3.1, chapter 3 for more detail) aims to identify and improve recognition about remarkable land-use systems and landscapes that have long provided various ecosystem services while contributing to biodiversity conservation and maintenance of Indigenous and local knowledge (FAO, 2010; Lu & Li, 2006; Nahuelhual *et al.*, 2014).

5.4.1.6 Telecouplings

Achieving global sustainability goals will likely require a targeted focus on the distant effects of local actions (telecouplings, such as spillover effects). Many existing environmental policy frameworks enable jurisdictions to meet targets by externalizing impacts to other jurisdictions (e.g., national greenhouse gas emissions and water use can and have been reduced in part by importing GHG and water-intensive agricultural commodities rather than producing them). While these allowances may have benefits, global sustainability will require assessing, addressing, and closing these loopholes.

Background

Systems in distant places across the world are increasingly interconnected, both environmentally and socioeconomically. The term telecoupling was created to describe socioeconomic and environmental interactions between multiple coupled systems over distances (Liu *et al.*, 2013). The concept of telecoupling is a logical extension of coupled human and natural systems because it connects distant systems instead of just studying individual systems separately or comparing different systems.

Telecoupling is an umbrella concept that encompasses many distant processes, such as migration, trade, tourism, species invasion, environmental flows, foreign direct investment, and disease spread. It expands beyond distant socioeconomic processes such as globalization by explicitly and systematically including environmental dimensions, and expands beyond distant environmental processes such as teleconnection by explicitly and systematically including socioeconomic dimensions simultaneously. As such, telecoupling emphasizes reciprocal cross-scale and cross-border interactions (e.g., feedbacks). It also helps to better understand interactions among multiple distant processes (Liu *et al.*, 2015a). Many telecouplings have existed since the beginning of human history, but their speed is much faster, their extents much broader, and their impacts much larger than in the past. Furthermore, current telecouplings occur in an entirely new context with many more people and more tightly constrained resources than ever before. Telecoupling can affect biodiversity and nature's contributions to people in distant locations and across local to global scales, with profound implications for the Aichi Biodiversity Targets, Sustainable Development Goals, and the Paris Agreement.

Spillover effects have been largely overlooked. For example, for international trade, the focus has been usually on impacts on trade partners. Several studies have reported spillover effects (also called offsite effects or spatial externalities) (e.g., Halpern *et al.*, 2008; van Noordwijk *et al.*, 2004). Placing spillover effects under the telecoupling framework can facilitate holistic understanding and management of the effects, as it helps to not only uncover the effects, but also connect them with causes and agents as well as flows across all relevant systems.

Evidence

As illustrated in Supplementary Table 5.4.4, many studies have demonstrated impacts of telecouplings on nature and nature's contributions to people. International trade has substantial impacts on ecosystem services and biodiversity in exporting countries (Lenzen *et al.*, 2012). Traditional trade research has focused on socioeconomic interactions between trade partners at the national scale, with some separate studies centered on environmental impacts (e.g., DeFries *et al.*, 2010; Lambin & Meyfroidt, 2011). More recently, studies have also showed that patterns of international investments through tax havens also have a direct impact on biodiversity loss in commodity-producing regions such as the Amazon (Galaz *et al.*, 2018). Such impacts result from land conversion from natural cover such as forests to crops (Brown *et al.*, 2014), or from pollution of water or air. It is clear that importing countries obtain environmental benefits (e.g., land allocation for biodiversity conservation and restoration rather than food production) at the expense of environmental degradation in exporting countries (Galloway *et al.*, 2007; Lenzen *et al.*, 2012; Moran & Kanemoto, 2016). For example, imports of food and other goods often have associated ecological footprints in producing regions (MacDonald *et al.*, 2015).

Spillover effects occur all over the world. These effects can be positive or negative, socioeconomic and/or environmental. They can be more profound than effects within the systems being actively managed. Evidence so far indicates that spillover effects are largely negative, such as degrading distant biodiversity, ecosystems and ecosystem services. In fact, much of the environmental impacts in many nations stem from activities driven by distant demand (e.g., through the production of goods for export; Halpern *et al.*, 2008; also see 5.4.1.2). Spillover effects are so prevalent that even policies intended to enhance regional or national sustainability can be perverse by shifting pressures to other

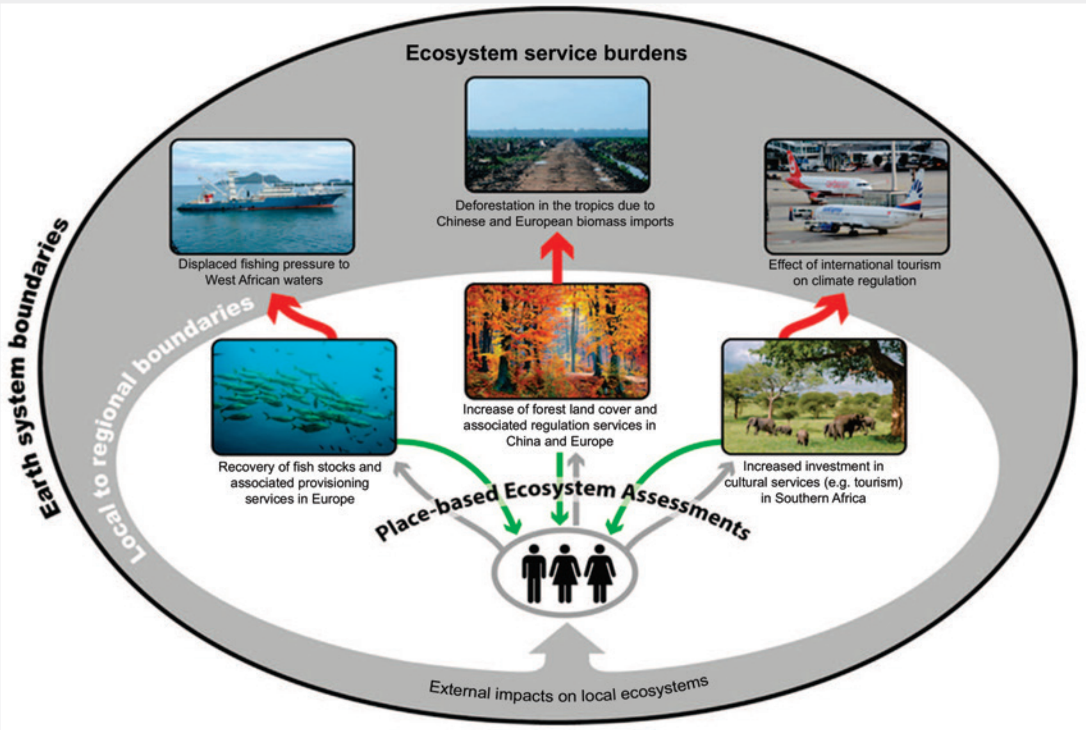

Figure 5 9 **Examples of telecoupling effects, in this case via unintended consequences associated with place-based ecosystem assessments.**

Current ecosystem services assessments focus on the benefits, trade-offs and synergies provided by ecosystem services within a delimited (often jurisdictional) boundary (green arrows) and the impacts that human activities have over such ecosystem services therein (grey arrows). Ecosystem assessments thus tend to overlook off-stage ecosystem service burdens (negative impacts on ecosystem services elsewhere; red arrows) of place-based management decisions and their feedbacks (e.g., due to climate change, bottom arrow re-entering the smaller white ellipse). Figure from Pascual *et al.* (2017b).

places (Pascual *et al.*, 2017b). Those other places may have lower environmental standards (Liu & Diamond, 2005) but richer biodiversity. For example, Sweden reduced rates of logging in Swedish forests, which increased imports from countries with greater forest biodiversity. Sweden also reduced oil use by substituting biofuels derived primarily from Brazilian sugar cane ethanol (Bolwig & Gibbon, 2009).

Even conservation efforts can generate negative spillover effects **(Figure 5.8)**. To conserve Amazonian forests, two supply-chain agreements (i.e., the Soy Moratorium and zero-deforestation beef agreements) have been implemented in the Amazon. Their implementation has substantially reduced deforestation in the Amazon but increased deforestation in the Cerrado (e.g., a 6.6-fold increase in Tocantins State of the Cerrado) (Dou *et al.*, 2018). The US and European Union countries implemented biofuel mandates to reduce their domestic carbon footprints, but these significantly changed land use and increased carbon footprints elsewhere (e.g., Africa, Asia) (Liu *et al.*, 2013).

Possible points of action

International agreements such as the Convention on International Trade in Endangered Species Flora and Fauna (CITES) and Reducing Emissions from Deforestation and Forest Degradation (REDD+) deal with distant interactions (e.g. trade), but could do so more effectively (Liu *et al.*, 2013). For example, telecoupling effects could be systematically integrated into processes of evaluating and revising the Convention and REDD+. Parties who are responsible for telecoupling effects can be identified and held accountable for negative effects (e.g., providing payment or compensation). New agreements may be needed to incorporate telecoupling effects.

Trade policies could be refined to disincentivize trade that entails negative spillover effects. Policies might restrict imports of products whose production entails large environmental damages (perhaps in part because the exporting country has very low environmental protection standards; Liu *et al.*, 2016). For example, the EU's Forest Law Enforcement, Governance and Trade (FLEGT, http://www.euflegt.efi.int/) bans the import of illegally harvested timber as a step to reduce spillover effects, which could be applied to other sectors. Such policies could be designed to raise standards by providing some assistance for nations lacking sufficient environmental governance regimes without punishing nations already suffering from extreme poverty.

Conservation scientists, policymakers and practitioners can also aid global sustainability by considering telecoupling effects in the design and evaluation of conservation policies, paying attention to negative effects outside focal conservation areas. Analyses of outcomes of conservation policies could include spillover effects in addition to the effects on the system in question.

5.4.1.7 Sustainable technology via social innovation and investment

Pathways to a desirable societal future entail a regime change first towards technologies that reduce environmental impacts and then towards those with net-positive impacts. These technological and social innovations must be proactive (not only reactive) and go well beyond the scope of traditional environmental protection policies. A sustainable economy fosters socio-technological systems that maintain, support and apply ecosystem services and biodiversity through different forms of nature-based solutions, including by galvanizing private, but public welfare oriented, investment in nature.

Background

"Technology" is a container term for various approaches to enhance human performance. Scientific assessments of technology neither idealize nor demonize it from an environmental perspective, but consider it as an ambivalent means of achieving particular goals (see, e.g., Davies, 2014; Walker & Shove, 2007).

Whereas technological development and innovation-friendly economies were long combined with a belief in the superiority of technological civilization over nature, insights about the indispensability of ecosystem services and their cost-effectiveness (e.g., Chichilnisky & Heal, 1998) have produced new expectations of technological innovations (see Geels *et al.*, 2015). Even though technological progress cannot be considered a panacea for global sustainability problems, it can contribute to overcoming sustainability challenges under particular circumstances. First, precaution can contribute to minimize or prevent negative or ambivalent outcomes of technologies (see 5.4.2.3; Renn, 2007). Second, shedding past dependencies on unsustainable or less-sustainable technologies contributes to promote innovations and spur new economic opportunities while avoiding pathways that collectively pose non-negligible risks of irreversible effects in ecological systems (Foxon, 2007). Third, ensuring that technological enhancements and resulting efficiency do not stimulate increases in new types of consumption of unsustainable goods or services (Allan *et al.*, 2006; Dimitropoulos, 2007; Herring & Roy, 2007; Lambin & Meyfroidt, 2011).

Industry and businesses are major drivers of ecosystem change. Such positioning highlights the potential for their role in reducing these impacts, which must go beyond marginal improvements (Scheyvens *et al.*, 2016). Earlier sections of this chapter (5.4.1.1, 5.4.1.2) address the needed decoupling of consumption from well-being. Innovations in technology and its usage can play a key role here. Beyond technology, innovation in business models and accounting procedures are central to incorporating environmental externalities into economic decisions. Furthermore, cross-sectoral partnerships and collaborative efforts (e.g., public-private impact investments for public benefit, and multi-stakeholder platforms for commodities that exist for palm oil, sugar, cotton, soy and rubber) facilitate implementation and mainstreaming in business and practice (Dyllick & Hockerts, 2002). Healthy skepticism about the execution of these is merited to guard against greenwashing (see Dauvergne & Lister, 2013), and effective design incorporating monitoring, adaptation and commitment to continued improvement can ensure real on-the-ground impact—but such efforts take time.

The particular role of the private investment sector in supporting sustainable development innovations is subject for debate, both in terms of the needed capital for technological development, and realization of alternative financial mechanisms. Historically, governments fund initiatives that generate public welfare goods, or devise policy and regulation to promote investment or facilitate growth in certain sectors, as has been seen with subsidies (e.g., 5.4.2.1). The scale of transformation and investment required to achieve the Sustainable Development Goals is not possible through government action alone (see SDG 17 on partnerships). Impact investing is a rapidly growing financial mechanism where private and public-private arrangements seek to generate both economic and social returns (Oleksiak *et al.*, 2015). Such investments may come in the form of direct support of a business or project, indirectly through funds managed by an intermediary, or green or social impact bonds. Governments and foundations are often key partners whose participation helps leverage capital from private sources, creating a multiplier effect, though questions remain as to how such arrangements can be implemented in the conservation sector when an existing commodity (such as agriculture or fisheries) is not present (Olmsted, 2016).

Evidence

Socio-technological innovations play a key role for transformations towards sustainability. From the scenario reviews and nexus analyses we know that technological advances in the food system and agriculture are central to feeding the world's future population and enhancing the conservation and sustainable use of nature (5.3.2.1) and to improving water quality and water use efficiency and increase storage (5.3.2.4). Energy production from various bioenergy systems as well as climate change adaptations depend on further socio-technological developments (5.3.2.2). Resourcing growing cities while maintaining underpinning ecosystems and their biodiversity is a complex socio-technological challenge across spatial and social scales (5.3.2.6).

Responsible investment in industries that directly influence natural resources and assessment metrics that go beyond short-term economic profitability will be critical to achieving the nature-related SDGs in particular. Given the broad scope of socio-technological systems, such responsible investment strategies can contribute to the emergence of a new techno-economic paradigm of sustainability (Perez, 2002), if incentives and regulations are reconfigured according to the socioecological underpinnings of the global economy (5.4.2.1-5). First steps have already been achieved by acknowledging that unsustainable technology poses large and potentially unforeseeable risks to the ecological embeddings of societies (Altenburg & Assmann, 2017). Though not expanded upon here, these processes need to address cultural diversity, social justice and public interests (see 5.4.1.5; Beumer *et al.*, 2018).

Transformations of various sectors (including energy technology, transportation, and built infrastructure generally) are beginning to attend to climate change considerations but have yet to address as mainstream a comprehensive suite of biodiversity and ecosystem service considerations (CBD, 2010; Cowling *et al.*, 2008); if they are not addressed directly, such nature-related considerations are likely to be further undermined by technological and sectoral evolution (Gopalakrishnan *et al.*, 2017). Increasing returns from investments in socio-technological niche innovations entail increasing risks of promoting less sustainable technologies and/or institutions, since already funded projects are treated preferentially at the expense of potentially superior alternatives (Foxon, 2007).

The 'rebound' of efficiency gains can be tackled in the transition phase of an incremental innovation by taxation, regulation or other impulses for consumption change (see, for example, Herring & Roy, 2007). Here, sociocultural framings, norms, worldviews and relational values influence the outcomes of socio-technological innovations enormously. Nevertheless, these factors remain largely overlooked in studies on sustainable socio-technological transformations (see Beumer & Martens, 2010).

Socially responsible and impact investing sectors are growing rapidly (GIIN, 2017), though environmental and conservation projects represent a fraction of impact investments; and impact investments currently represent a tiny share of global private capital markets. The limited application to date in the conservation sector is due to a lack of investable projects at scale, as well as challenges assessing and attributing impact in complex ecological systems (Olmsted, 2016). While there are a few large and headline grabbing arrangements, such as the Seychelles debt swap that will result in 400,000 km^2 of marine protected areas in the coming 5 years, such outcomes take years of negotiation and involve an array of public and private partners (NatureVest, 2018). Impact investments need not be so complex, but such examples highlight the potential scale of impact.

Possible points of action

Socio-technological sustainability innovations can be stimulated by incentives (e.g., Costello *et al.*, 2008; Mulder *et al.*, 1999; see also 5.4.2.1), but can also be initiated in real world experiments (Liedtke *et al.*, 2015; Nevens & Roorda, 2014; see also 5.2). Technological enhancements in companies can be supported by new innovation methods (Gaziulusoy *et al.*, 2013). Furthermore, implementation of a precautionary approach encourages proactive orientations towards sustainability in socio-technological innovation processes (Leach *et al.*, 2010).

Since affordability is a key to diffusion of new technologies (e.g., Mazumdar-Shaw, 2017), diverse financial instruments, including public financing and sharing technologies, contribute to overcoming unsustainable socio-technological systems rapidly (Foxon & Pearson, 2008; Stirling, 2008; Technology Executive, 2017). Public deliberation and transparent decision-making which involve experts, stakeholders and interested citizens generates social robustness of envisioned changes (Bäckstrand, 2003) and helps to avoid technological and institutional dependencies (van den Daele, 2000).

Every transformation process in which new technologies are established generates winners and losers. This is not only true for species (Egli *et al.*, 2018), but also for groups and individuals (e.g., O'Brien & Leichenko, 2010). Blockades to sustainable socio-technological solutions and lock-ins might be considered as strategies for avoiding losses of socioeconomic status. Innovative changes in technological policy and regulation and in incentive structures could deepen and accelerate steps towards sustainable socio-technological systems by simultaneously addressing both the demand for and supply of innovation (Jaffe *et al.*, 2005).

While there has been increased emphasis on sustainability reporting, and efforts such as the Global Reporting Initiative aim to streamline and facilitate reporting, climate metrics receive significant attention and the lack of emphasis on ecological systems is of particular concern (Milne & Gray, 2013). A study of corporate commitments to reduce deforestation highlight the challenges to meeting targets due to obstacles including leakage, lack of transparency, traceability, and selective adoption (Lambin *et al.*, 2018). These authors and others recommend increasing partnerships and arrangements between NGOs, businesses, and governments to co-create solutions and work to reduce impacts. The emergence of legal arrangements to loosen profit-maximizing constraints of corporations have promoted social business and investments in long-term sustainability that may not have been viable previously. As consumers and investors demand transparency, communication of impact and information-sharing can hold organizations accountable. Coordinating efforts across the public and private sector can help develop relevant policy, regulation, and incentives that provides stability and confidence for business and investors in new technology and innovation (e.g., Dauvergne & Lister, 2012). Corporate targets can incentivize innovation in supply and value chains (e.g., improving transparency with new technologies). Effective transformation on the ground may require national level intervention, for example, policies to support small producers who may not otherwise be able to transition as quickly or effectively. Voluntary public commitments permit early movers to demonstrate a business case for sustainable transitions, which can be bolstered by public sector support (e.g., Tayleur *et al.*, 2017). Full-cost accounting and policy shifts including changing accounting rules to include natural capital as an asset class have been shown to facilitate long-term investment in ecosystem services (Municipal Natural Assets Initiative, 2017).

5.4.1.8 Education and transmission of indigenous and local knowledge

Education and knowledge transmission are often heralded as a route to sustainability through maintenance or change in behaviours and attitudes, but their role in sustainability is even more fundamental, as a precursor to well-functioning societies. Further, education will only serve either role if conceived much more broadly than as imparting information. Rather, education that leads to sustainable development and enduring change in knowledge, skills, attitudes, and/or values builds from existing understandings, fosters social learning, and embraces a "whole person" approach. Environmental education can enhance values such as connectedness, care, and kinship. Transmission of indigenous and local knowledge can serve all the roles above, including maintaining invaluable knowledge and experiences about ecological processes, but it is also a keystone to cultural integrity and the maintenance of collective identity.

Evidence

Education, as the broad transmission of knowledge and capabilities, is widely recognized as essential for stable, well-functioning societies (Nussbaum, 2000; Otto & Ziegler, 2010; Sen, 1999). Thus, education—*in and of itself*—is a crucial precursor of sustainability (Sachs, 2015). Though education systems have sometimes served to inculcate particular norms and attitudes (King & McGrath, 2004), some educators and scholars have for centuries recognized and taken steps to deal with the inherent ethical complexities of teaching to develop engaged citizens (e.g., Dewey, 1975; Hug, 1980).

A brief yet crucial point is the demonstrated importance of education for girls and women. Increased rates and quality of education for girls and women correlate with higher levels of gender equity and lower birth rates, both of which are components of pathways to sustainability (UNICEF, 2003; see also 5.4.1.2 and 5.4.1.4).

Beyond the crucial importance of indigenous and local knowledge for cultural integrity and identity, ensuring the transmission of this knowledge and practices is key to sustainable pathways. Over millennia, IPLCs have developed and integrated invaluable knowledge and experiences about ecological processes, environmental management, production systems, as well as institutions supporting the sustainable use of resources (Nadasdy, 2007; Taylor, 2009; Tuck *et al.*, 2014; Turner, 2005; Vickery & Hunter, 2016). Many landscapes around the world, and much global agrobiodiversity heritage, depend on the knowledge and cultural memory held by IPLCs and other farmers, hunters, fishers, foragers, herders, and pastoralists, etc. Continued transmission of these forms of knowledge in varied and culturally appropriate ways (Cajete, 1994) maintains alternatives for managing landscapes and seascapes sustainably (5.3.2.3; 5.4.1.5).

Emerging insights from western literatures on education appear to be converging with lessons from indigenous and local knowledge transmission. As a first example, research demonstrates that the "deficit model" of education and communication, which assumes that people would think and act differently if only they had the right information, is rarely effective at creating lasting attitudinal or behavioural change (Dietz & Stern, 2002; Kollmuss & Agyeman, 2002). More effective educational approaches—those that are more likely to foster fundamental and long-term change in knowledge, skills, attitudes, and/or values—encompass prior knowledge (e.g., existing understandings), social interaction (e.g., interpersonal relationships and collective learning), and affective as well as cognitive dimensions (e.g., emotional responses to what is learned; Heimlich & Ardoin, 2008; Wals, 2011). Based on these findings, fields related to environmental education, including nature conservation education and education for sustainable development, have moved away from an "information delivery" model to more integrated models that collaboratively explore the intricate links between environmental and social equity and empower learners as change agents.

Broad education and knowledge transmission literatures have identified that effective education, including that for sustainability, involves two interrelated components: process and content. The former is crucial, but often overlooked. Process involves the ways education is carried out, in other words, the approaches and how teaching and learning occur. Diverse theories of learning emphasize different aspects of the learning process (Merrian & Bierema, 2013). A few commonalities emerge, and three aspects of learning theory (detailed below) are particularly relevant to issues of sustainability.

The first commonality of learning theory is the importance of recognizing and responding to learners' context, experience, and existing understandings. A helpful metaphor here follows directly from constructivist learning theory, understanding is constructed from and upon "blocks" of what is already known and if existing understandings must be changed, that must be dealt with, not ignored. In sustainability-related education, this concept is paramount, it coincides with the importance of locally based solutions that account for diverse contexts.

A second commonality is the role that social interaction plays in learning. This focus on social dimensions of learning takes two primary forms: the idea that much learning occurs via observing others (Bandura & Walters, 1977; Rogoff *et al.*, 2003) and the idea that learning occurs collectively, in and by social groups (Rogoff, 1994; Wals, 2007). These social interactions may be particularly important for the transmission of indigenous and local knowledge (Berkes & Turner, 2006; Turner & Turner, 2008). The importance of social interaction for sustainability education manifests in many ways, including the strong role that social norms play in fostering sustainable behaviour (Miller & Prentice, 2016) and the substantial success of initiatives that engage social learning for sustainability (Wals, 2007).

A third commonality addresses the relevance of attending to the "whole person" in learning. The whole person approach emphasizes that education is about both cognitive and affective aspects of the learner, that education must think not only about cognitive development, but must also attend to the crucial role that emotion can play in learning (Podger *et al.*, 2010). This holistic approach has been central to education in IPLCs for millennia. These emotional aspects may be particularly important in sustainability-related education, which can involve strong emotions such as despair and hope (Hicks, 1998; Li & Monroe, 2017; Newman, 1996).

Content is the second pillar of sustainability education. Though content may seem more straightforward than process, decisions about content, what to include and exclude from educational initiatives, are crucial. Content encompasses knowledge, concepts, and skills that are relevant to sustainability. Content that is central to most recent frameworks of environmental and sustainability education includes the following: social justice and the centrality of equity to sustainability; participatory learning and engagement with local communities (both ecological and social); citizenship skills, such as knowledge and empowerment related to collaboration, dialogue, and democratic processes; interconnectedness and systems thinking; and attention to multiple scales (spatial, temporal, and organizational) (Tilbury, 2011).

Possible points of action

Given that a common challenge to sustainable behaviour is that people default to decision-making based only on technological or economic feasibility, sustainability-related education can develop understanding of the complexities of, and synergies between, the issues threatening planetary sustainability, and encourage consideration of complex options and trade-offs. The long timescales over which people's orientations and priorities become established, coupled with the many social and personal influences on these orientations and priorities, make study of the impact of sustainability-related education difficult. Even so, research suggests that time spent during childhood in outdoor or natural environments with respected adults can be an important motivator for learning about these complex issues and taking sustainability-related action in adulthood (Chawla & Cushing, 2007). Though results about the relations between connection to nature and behaviour are varied; connection to nature, which is often but not always established in childhood, in some cases correlates with increased pro-environmental behaviour (Geng *et al.*, 2015; Gosling & Williams, 2010; Mayer *et al.*, 2008).

For IPLCs, the educational system can be the basis for strengthening a political and cultural project that incorporates traditional and novel perspectives on management, use, and maintenance of existing resources in these communities. Some see an urgent need to recognize the importance and enhance the transmission of indigenous and local knowledge, both intergenerationally and among different societal groups, as a complement to mainstream education—including to maintain crucial relationships with nature and values of responsibility and stewardship associated with those (Chan *et al.*, 2016; Chan & Satterfield, 2016). Ideally, these two forms of knowledge can be integrated, but often formal education tends to be favoured and in some cases negates the value of local forms of knowledge. Education targeted at IPLCs can develop skills required to, for example, serve in government roles or innovate in fields such as production, trade, and management, *while maintaining traditions, values and culture*. At the same time, incorporating principles and content from indigenous and local knowledge would enrich and improve all education (McCarter *et al.*, 2014; World Bank, 2015).

Environmental education can lead to a variety of outcomes supportive of sustainability, including knowledge, attitudes, and skills (Stern *et al.*, 2014). It can also enhance values such as of connectedness, care, and kinship (Britto dos Santos & Gould, 2018). That said, the fields of environmental and sustainability education are home to many discussions of the extent to which education should explicitly encourage particular values or behaviours (Hug, 1980). Though opinions on the proper course of action differ, the most common approach is for environmental education to encourage active and informed citizenship. This citizenship inherently encompasses the ability to understand and assess one's own values (virtues and principles) and those of the society in which one lives (Tilbury, 2011). Increasing awareness of connectivity in the environmental crisis and new norms regarding interactions between humans and nature would support transformative change The goal of this work is to provide tools that allow people to engage in respectful, thoughtful, and informed negotiations toward decisions and actions that lead to a sustainable future (Huckle *et al.*, 1996; Tilbury & Wortman, 2004).

5.4.2 Levers for Sustainable Pathways

5.4.2.1 Strategic use of incentives and subsidies

Achieving SDGs and Aichi Biodiversity Targets will likely require a continued evolution of subsidies (including discontinuing harmful subsidies) and incentive programs to foster conservation and stewardship practices while cultivating appropriate norms and values. Such programs can be part of effective policy mixes, involving both positive and negative incentives through regulations and market-based instruments.

Background

While subsidies are a form of incentive, due to their prevalence as a policy tool and history of challenges, we see benefit in distinguishing them from other incentive types. Note also, that although incentive programs are often considered to trigger behaviour change by providing an incentive, a diverse body of literature strongly suggests that the incentive to conserve or restore may already exist and that 'incentive' programs may work best by removing financial and regulatory barriers (Kosoy *et al.*, 2007; Stoneham *et al.*, 2003; Wilcove & Lee, 2004).

Evidence

Many scenario and pathway analyses identified the importance of shifting incentive structures, either by removing perverse subsidies or adding new positive incentives, especially studies focused on climate action, energy systems, or water. For example, Schandl *et al.* (2016) explored the implications of imposing a global carbon price, which in their model created incentives for nations to invest in renewable energy generation. Carnicer & Peñuelas (2012) demonstrated the power of funds raised through small negative incentives, showing that a small global tax on financial transactions of 0.05% could provide funds required for widespread deployment of renewable energies. McCollum *et al.* (2012) concluded that incentive mechanisms are key to transforming the global energy system, including targeted subsidies to promote specific "no-regrets" options (e.g., microcredits and grants for low-income populations to buy low-emission biomass and low-emission biomass and Liquefied Petroleum Gas (LPG) stoves).

Subsidies and other so-called incentive programs are implemented to shift institutional and individual practices, which is a key component of successful pathways, under two conditions. The first is that such incentive programs are implemented as components of policy mixes (Barton *et al.*, 2014; Bennear & Stavins, 2007; Porras *et al.*, 2011), in which regulations are also employed to set norms and provide negative incentives. In some contexts, the incentive program or subsidy is the positive element that makes a regulation politically feasible, where the regulation is the key factor in shifting practice—e.g., as apparently the case for the national payments for environmental services (PES, or 'PSA' in Spanish) program and deforestation ban in Costa Rica (Daniels *et al.*, 2010; Fagan *et al.*, 2013; Legrand *et al.*, 2013; Morse *et al.*, 2009; Pfaff *et al.*, 2009; Porras *et al.*, 2013; Robalino *et al.*, 2015).

Incentive programs play especially helpful roles in pathways when executed so as to avoid the historic pitfalls resulting in adverse environmental consequences. The evidence from natural and social sciences reveals two broad classes of failings with regard to the role of incentives and subsidies in resource management. First, a large number of incentives and subsidies are intended to encourage employment and production but have unintended large-scale impacts on biodiversity and ecosystem services (e.g., Milazzo, 1998; Sumaila & Pauly, 2007). In addition to direct negative effects on ecosystems, by distorting market signals to boost production, some subsidies promote overproduction that can fuel overconsumption and drive a vicious cycle (5.4.1.2, 5.4.2.1).

Subsidies are important features of major industries and their environmental impacts. Concerning marine fish biodiversity, for instance, an estimated $35 billion in subsidies (30–40% of estimated gross revenues from the sector) is provided to the global fishing sector annually. Nearly 60% of this is classified as harmful subsidies, i.e., those that ultimately stimulate over-capacity and overfishing (Heymans *et al.*, 2011; Sumaila *et al.*, 2016). Agricultural subsidies intended to stimulate growth in domestic markets and competitiveness in exports have likewise led to unintended ecological consequences. Corn subsidies for biofuel in the United States increased corn production and decreased soy, significantly increasing global soy prices, incentivizing Amazon deforestation as soy-related land conversion dramatically increased in Brazil (Laurance, 2007; Westcott, 2007).

In many cases, even incentives and subsidies that are intended to encourage conservation and stewardship behaviours can result in unintended negative effects at either individual or collective scales (Chan *et al.*, 2017b; Vatn, 2010). A good example here are so-called buyback or decommissioning subsidies. Millazzo (1998) considered these to be 'green' subsidies because the goal of governments who implement buyback subsidies is to reduce fishing capacity in overfished fisheries. But what often happens is that vessels supposedly retired quickly seep back into the fishery (Holland *et al.*, 1999). Furthermore, fishers may anticipate the implementation of a buyback subsidy, which can motivate them to accumulate additional fishing capacity so they can sell it later for profit in a buyback programme (Clark *et al.*, 2005).

Incentives and subsidies intended to encourage conservation and stewardship actions can also backfire by crowding out inherent motivations and by assigning or reinforcing notions of rights and responsibilities that may be counterproductive for long-term sustainability (Chan *et al.*, 2017b; Vatn, 2010). There is strong experimental evidence that when people have inherent motivations to undertake an action beneficial for biodiversity and ecosystem services, the introduction of a monetary incentive can sometimes undermine those inherent motivations (Rode *et al.*, 2015), with potentially damaging consequences for long-term outcomes. However, incentive programs can also sometimes strengthen pre-existing motivations (i.e., 'crowd-in' inherent motivations; Rode *et al.*, 2015), and can be designed to do so while articulating and reinforcing values and norms of stewardship and responsibility (Chan *et al.*, 2017b).

Possible points of action

Strategic incentive programs are pertinent to a wide range of actors including private industry (e.g., forestry, agriculture, resource users of all kinds), NGOs, IPLCs, and governments of all kinds. Programs like payments for ecosystem services (PES) can be initiated by a wide range of actors for private gain and also improved environmental outcomes (Chan *et al.*, 2017a).

Programs providing incentives to undertake positive actions may be less prone to perverse consequences than those incentivizing stakeholders to refrain from taking damaging actions. Programs designed as flexible grants and awards may be more successful at articulating socially desirable rights and responsibilities, and 'crowding in' inherent motivations, than those that provide set payments for particular metrics (e.g., trees planted or not harvested) (Chan *et al.*, 2017a).

On a general level, the rules and regulations governing day-to-day decision-making can be adapted to create the right incentive structure for transformative changes (PBL, 2012). This would include abolishing perverse incentives (e.g., capacity enhancing subsidies: Sumaila *et al.*, 2016; Sumaila & Pauly, 2007; WBCSD, 2010) and introducing environmental factors in current pricing systems, e.g., green taxation (e.g., Daugbjerg & Pedersen, 2004).

5.4.2.2 Integrated management and cross-sectoral cooperation

Integrated management is widely recognized as an important mechanism to realize co-benefits and avoid trade-offs among competing priorities involving food, biodiversity conservation, freshwater, oceans and coasts, cities and energy, as analysed above (5.3.2). Achieving multiple SDGs and Aichi Biodiversity Targets entails policy coherence and the mainstreaming of environmental objectives across institutions within and among jurisdictions (e.g., fishing, transportation, shipping, oil and gas, renewable energy). Not all action towards a given objective will simultaneously benefit all other objectives, so an integrated approach enables harmonization that achieves targets without undermining others. Additionally, achieving global objectives will take coordinated action among disparate governing bodies.

Evidence

Almost all reviewed scenario and pathway studies called for integration and harmonization of policies and programs across sectors, agencies or jurisdictions. As an example, Fricko *et al.* (2016) concluded that an integrated approach to developing water, energy and climate policy is needed, especially given anticipated rapid growth in demand for energy and water. Quite differently, McCollum *et al.* (2012) included one pathway with integrated implementation of energy efficiency measures across all major sectors, leading to substantial reduction in energy demand. Integrated management is also widely recognized as key for availability, distribution and access to water (Cosgrove & Rijsberman, 2000), including as implemented by national governments across a broad policy spectrum including agriculture, food security, energy, industry, financing, environmental protection, public health and public security (WWAP, 2015).

Environmental management typically follows a series of demarcations most often along geopolitical boundaries and human constructs of the environment. First, management agencies are often constrained by jurisdictional boundaries that do not correspond with meaningful ecological transitions (McLeod & Leslie, 2009; Tallis *et al.*, 2010). Because of telecoupling across boundaries (discussed in 5.4.1.6), integrated policy and governance is key to managing effectively. For example, the Rocky Mountains of North America are managed by different countries' natural resources, environment and parks agencies (Canada and the USA), and by different provinces and states within these countries, without overarching agencies to consider management across these divisions. Cross-jurisdictional efforts like the Yellowstone to Yukon Conservation Initiative are important for gathering a wide range of stakeholders across this large region; transboundary management would go further, reconciling multiple management goals from multiple agencies for the Rocky Mountains (Levesque, 2001).

Second, ecosystems are often managed, and studied, separately (O'Neill, 2001). Perhaps the most prominent example of this type of division is the separate management of oceans versus land (Álvarez-Romero *et al.*, 2011). Despite clearly important connections in the land-sea interface—terrestrial processes affect oceans and marine processes affect the land (Álvarez-Romero *et al.*, 2011; Hocking & Reynolds, 2011; Tallis, 2009)—these divisions persist.

Third, management is often conducted separately on different important human uses, such as government departments dedicated to parks, protected species, fisheries, agriculture, energy and development (Becklumb, 2013). In some cases, this means that environmental impacts of overlapping human activities are managed separately; in other cases (e.g., protected areas), multiple activities are managed simultaneously, but often only within tight boundaries whereas environmental impacts transcend these. Environmental impacts and risks often stem from a variety of different activities, but accumulate (Halpern *et al.*, 2008). By dividing environment management according to different uses and different goals, important interactions among ecosystem components may be ignored. For example, management plans targeting recovery of predators or higher trophic level fisheries will be more effective if management also targets recovery of prey species (Samhouri *et al.*, 2017).

Finally, paradigms of environmental management are marked by conceptual divisions, whose integration would also help achieve sustainability objectives. For decades, western environmental management has treated human interaction with the environment mainly as a source of negative impacts, when in fact humans are in many cases integral components beneficial to ecosystems functioning (Hendry *et al.*, 2017; Higgs, 2017). Human activities often can transform otherwise inhospitable ecosystems to productive food growing habitats (Higgs, 2017), and fishing activities, if regulated, can sustain fish populations for harvest (Dowie, 2009; Jacobsen *et al.*, 2017). Yet, the view that humans are exogenous to natural systems has led to a series of important negative effects. As discussed above (5.4.1.5), there are numerous examples of conservation and management agencies, with power and authority over local institutions, that have moved to displace local populations from the ecosystems that, in many cases, are conserved because of them (Dowie, 2009), discrediting local knowledge about ecosystems management (Fischer, 2000), and imposing top-down regulations over institutions that have co-evolved with local ecosystem dynamics (Ostrom, 1990). Management mechanisms to attend to local concerns and integrate local knowledge can both provide valuable information and increase legitimacy and effectiveness of management.

Siloed management explicitly excludes interactions that can affect management goals. One example is the independent management of shipping, energy production, and coastal development, and the cumulative impacts this has had on the southern resident orca ('killer whale') population (Ayres *et al.*, 2012; Murray *et al.*, 2016) in the Salish Sea (in southeastern British Columbia, Canada and northern Washington State, USA). Incorporating risks to species and systems that these whales depend on can greatly increase understanding of risk (e.g., Murray *et al.*, 2016). In most cases, however, knowledge of risks to ecosystem services deriving from different human activities and infrastructure is piecemeal and insufficient for ecosystem-based management (Mach *et al.*, 2015). For long-term sustainability of resources and environments, cross-sectoral management is key to addressing multiple goals (Harrison *et al.*, 2018).

Recent analysis of interrelationships between SDG targets provides insights into how to integrate policy towards achieving multiple goals. For instance, it suggests that achieving the ocean targets within SDG 14 has the potential to contribute to all other SDGs (Singh *et al.*, 2018). Moreover, ending overfishing and illegal fishing alone (SDG 14.4) can contribute to several other SDG targets. Increasing economic benefits to Small Island Developing States (SDG 14.7) could contribute to a suite of SDGs, depending on policy implementation and how benefits are distributed (e.g., whether marine development helps fund education (5.4.1.8)). In contrast, increasing the coverage of marine protected areas (SDG 14.5) can trigger trade-offs with other SDGs among the SDG 14 targets, because MPAs can limit access to needed local resources and decrease local peoples political power. However, these trade-offs can be avoided through proper consultation and implementation with local people (5.4.1.5), as in integrative policy planning.

Thus, integrated management is widely understood as a key mechanism to account for interactions, trade-offs and synergies between SDGs. Global scenarios underline this even though many challenges are beyond the capability of integrated assessment models (IAMs) and require additional consideration (e.g., globalization processes such as trade, migration or large-scale land acquisitions including land-grabbing).

Possible points of action

Integrating management across sectors is pertinent to a wide range of actors including private industry (e.g., forestry, agriculture, resource users of all kinds), NGOs (e.g., land trusts), IPLCs, and governments of all kinds. For example, diversified but integrated business models for forestry or farming operations may yield greater and more stable revenues as well as long-term environmental benefits (harvesting resources but also hosting tourists and other recreators, and participating in ecosystem service markets and incentive programs). However, integrated management approaches will be much more likely when encouraged or required by underlying regulations and influential private and NGO actors (e.g., insurance and reinsurance companies, companies exerting control over value chains, investors, lenders, certification systems and other standards).

Management efforts with cross-boundary provisions are often helpful (Levesque, 2001; McLeod & Leslie, 2009; Tallis *et al.*, 2010). Management across boundaries can also contribute to and benefit from Sustainable Development Goal target 17.16 (global partnerships for sustainable development, complemented by multi-stakeholder partnerships).

Laws requiring that management and policy (including protected areas and restoration efforts) state and reflect important spatial and temporal social-ecological dynamics may enable long-term cross-sectoral benefits (Kliot *et al.*, 2001; McLeod & Leslie, 2009).

Co-management arrangements and partnerships with informal environmental experts and users, may enable integration of important and time-sensitive information, enhancing legitimacy of and compliance for management plans (Dowie, 2009; Fischer, 2000).

Management plans may be more successful if they reflect multiple goals, potentially including the state of a resource/population as well as the uses of that resource (Lindenmayer *et al.*, 2000; McLeod & Leslie, 2009; Rice & Rochet, 2005).

5.4.2.3 Pre-emptive action and precaution in response to emerging threats

Sustainable pathways generally entail addressing risks well before system-specific proof of impact has been established.

Evidence

The scenario and pathway studies consulted involve a timely response to a variety of risks facing biodiversity and ecosystem services, either explicitly or implicitly. While scenarios do not generally detail the process of scientific study or the demonstration of proof, based on the long time lag between scientific focus on a phenomenon and consensus about causality, let alone proof (Oreskes, 2004), we can infer that most scenarios entail managing risky activities before establishment of proof that those activities cause particular harms. Furthermore, backcasting studies sometimes indicate that certain interventions require early implementation (Brunner *et al.*, 2016).

The need for early, precautionary action is also supported by arguments from theory, supported by a wide range of associated evidence. Many important challenges facing nature and its contributions to people involve several key complications of complex adaptive systems (numerous time-lags in social and ecological subsystems, multi-causality that impedes proof, and nonlinear responses that may appear slow until a threshold is passed, after which reversal may be impossible or impracticable; for more, see 5.4.2.4). These complications mean that empirical demonstration of system-specific cause-and-effect relationships is difficult (sometimes impossible), that it may take a long time, and that major and near-irreversible harms may have occurred before proof is established (e.g., Burgess *et al.*, 2013).

The various components of this argument from theory have considerable empirical backing. First, there is abundant evidence of time lags between ecological degradation and their societal consequences (e.g., Jackson *et al.*, 2001). This is exacerbated by interacting regime shifts at multiple scales (Leadley *et al.*, 2014). Second, ample evidence demonstrates that many changes in biodiversity and ecosystem services are the result of simultaneous action of diverse processes operating at multiple scales, which would impede the demonstration of any one factor as the cause of a given decline (e.g., Graham *et al.*, 2013; Levin, 1992; Marmorek *et al.*, 2011; Schindler *et al.*, 2003). Third, many systems exhibit thresholds (e.g., Folke *et al.*, 2004; Hastings & Wysham, 2010) combined with path-dependency (hysteresis, e.g., Graham *et al.*, 2015; Hughes *et al.*, 2010), which are difficult to reverse (Walker & Meyers, 2004) and the difficulty reducing stressors sufficiently to encourage reversal (Graham *et al.*, 2013).

This drawback of reactive management is particularly relevant for managing effects on “slow” system variables (variables that historically would generally have changed slowly, on evolutionary timescales), such as habitat availability. Such “slow” variables are often secondary concerns for stakeholders and managers more concerned with “fast” variables, such as annual fishery productivity, except where the habitat itself is widely appreciated (e.g., coral reefs; Pratchett *et al.*, 2014). However, should a slow variable pass a threshold, the system may shift rapidly to an alternate state, thus changing the dynamics of fast variables (Walker *et al.*, 2012). In such situations, even if the slow variable is restored to its previous level, the fast variables may be unable to return to their previous configurations due to the effects of path dependency.

The management of risks to slow variables is a key aspect of governing for resilience (Folke *et al.*, 2004; see also 5.4.2.4). However, as indicated above, it can be very costly if management waits for system change before acting to identify and manage risks. Due to their generally slower rates of change and susceptibility to threshold effects, slow variables in particular may often require precautionary approaches. This is the rationale for this specific lever as an issue that is separate but complementary to both integrated management (5.4.2.2) and management for resilience, adaptation, and transformation (5.4.2.4).

Possible points of action

Based on the above, it would appear that management, policies, and laws that place a strong burden of proof for the establishment of harm before requiring action are not conducive to long-term sustainability. Accordingly, a precautionary approach can be embedded in resource management and a diverse set of environmental policies and laws (e.g., Europe’s Registration, Evaluation, and Authorization of CHemicals (REACH) regulations). This point is pertinent to a wide range of actors including private industry (e.g., forestry, agriculture, resource users of all kinds), NGOs (e.g., land trusts), IPLCs, and governments of all kinds. However, precautionary approaches will be much more likely when encouraged or required by underlying regulations and influential private and NGO actors (e.g., insurance and reinsurance companies, companies exerting control over value chains, investors, lenders, certification systems and other standards).

Precautionary approaches have been subject of much debate (Stirling, 2007), but they have become accepted aspects of management in some respects. A precautionary approach is one of the principles of the UN’s voluntary Code of Conduct for Responsible Fisheries, for example, and thus has become established as a commonly invoked tenet of fisheries management. In the Alaska groundfish fisheries, for example, precaution has been integrated into the process by which allowable catches are determined, with estimates of maximum yield serving as a limit to be avoided rather than a target to be achieved; allowable catches are reduced from this limit following a series of steps that buffer against uncertainty, requiring greater reductions in catches in situations of less information (Witherell *et al.*, 2000).

A key precautionary mechanism is the maintenance of diversity. For instance, genetic diversity within and among species contributes substantially to ecosystem services, just as a diversity of species do. Genetic diversity within species maintains the potential for them to respond adaptively to environmental changes, thus facilitating and improving persistence in the face of environmental change. Diversity also maintains options for the future (NCP18).

The precautionary approach was not necessarily formulated to address issues of complex adaptive system management. However, it does provide a framework for the management of risks and uncertainty associated with complex social-ecological systems (Levin *et al.*, 2013), and thus represents an existing policy lever by which the challenges of complex adaptive system management may be addressed. Integrated Ecosystem Assessment may be useful for identifying appropriate early and pre-emptive actions (Levin & Möllmann, 2015), via a formal synthesis and quantitative analysis of relevant natural and socioeconomic factors in relation to specified ecosystem management objectives. Regardless, it is particularly important to avoid inaction (DeFries & Nagendra, 2017).

5.4.2.4 Management for resilience, uncertainty, adaptation, and transformation

Policies, programs and management agencies that seek optimal outcomes while assuming linear or equilibrium ecosystem dynamics are likely to result in undesirable surprises, as nature often operates in nonlinear ways. Policies and programs that are designed to be robust to uncertainty and to cultivate system resilience, including at the expense of program efficiency, may be more effective and efficient in the long term.

Evidence

Environmental management that seeks to maximize the extraction of a resource or population often backfires. System shocks and sudden changes can and generally will undermine effective management (Chapin III *et al.*, 2009). There are three ways in which the long term stability of an ecosystem can change that affect nature's contributions to people.

First, the consequences of ecological degradation may not be felt immediately but may manifest after a time lag. Historical overfishing has been linked to the collapse of coastal ecosystems, limiting their ability to provide resources for people (Jackson *et al.*, 2001). Similarly, the historic culling of wolves in North America has led to an abundance of coyotes and mesopredators, which has led to economic costs for ranching through predation on livestock (Prugh *et al.*, 2009).

Second, management to optimize a single goal can leave ecosystems vulnerable to disturbances. The literature on agriculture and forestry industry is replete with evidence of how management to maximize yield renders ecosystems vulnerable to pests and diseases (Meehan & Gratton, 2015; Taylor & Carroll, 2003). Future shocks to ecosystems in the form of invasive species and diseases can pose long term risks to managed ecosystems. The mountain pine beetle epidemic is a prime example, where management of forest landscapes for a single primary goal (timber extraction) resulted in monocultures of even-aged trees that facilitated a massive infestation that threatened both forest ecosystems and the forestry industry in western North America (Li *et al.*, 2005; Safranyik & Carroll, 2006). Often, this vulnerability to disturbance is due to managing ecosystems with little species and structural diversity (Meehan & Gratton, 2015). Conversely, there is ample evidence to show that incorporating ecological diversity in managed ecosystems can protect against diverse shocks and help maintain ecosystem services (Duffy, 2009; Oliver *et al.*, 2015; Tilman *et al.*, 2006a).

Third, many systems exhibit thresholds of change, meaning that the build-up of human pressure may lead to sudden large changes in an ecosystem (Boettiger & Hastings, 2013). These 'tipping points' and ecosystem state changes have been documented on land and sea (Folke *et al.*, 2004; Hastings & Wysham, 2010), and may be accompanied by 'hysteresis effects', whereby a change in ecosystem state is difficult to reverse because of path-dependency (Graham *et al.*, 2015; Hughes *et al.*, 2010; Walker & Meyers, 2004; see also 5.4.2.3). Ecological state changes can occur at multiple scales and interact, which only increases their severity and difficulty in reversing (Leadley *et al.*, 2014), increasing the importance of managing more broadly for resilience, transformation and uncertainty.

Many case studies point to state changes being a result of multiple processes operating at multiple scales, impeding the identification of any single factor as the cause of a deleterious change (Graham *et al.*, 2013; Levin, 1992; Schindler *et al.*, 2003). Changes to Earth's climate, landscapes, and seascapes are the result of a growing human imprint, and the cumulative impacts of human actions can be more important as drivers of change than any single action (Halpern *et al.*, 2015). Research on the major drivers of tipping points for ecosystems and ecosystem services often points to interactions between emerging climate change and local human pressures, indicating that some risks posed by dramatic ecological changes may be more prevalent in the future (Halpern *et al.*, 2015; Rocha *et al.*, 2015). Thus, management that explicitly accounts for nonlinear dynamics will be more important than ever.

Possible points of action

Management that includes goals to reduce vulnerability to long term shocks and tipping points may be more effective at preventing or mitigating disasters, thus reducing the waste of resources associated with recovery efforts and accruing private benefits as well as more diffuse public ones (both social and ecological). In contrast, management focused principally on optimizing resources or populations may achieve short-term gains at the expense of long-term productivity and stability.

As with early action (5.4.2.3), managing for resilience, uncertainty, adaptation and transformation is pertinent to a wide range of actors including private industry (e.g., forestry, agriculture, resource users of all kinds), NGOs (e.g., land trusts), IPLCs, and governments of all kinds. Again, resilience-focused approaches will be much more likely when encouraged or required by underlying regulations and influential private and NGO actors (e.g., insurance and reinsurance companies, companies exerting control over value chains, investors, lenders, certification systems and other standards).

Management may be more effective if it explicitly considers how the underlying ecology and physical processes support specific management goals, and the major threats to these goals (Kelly *et al.*, 2015). The consideration of nonlinear ecosystem dynamics provides vital insights into appropriate timings, windows of opportunities and risks and the financial viability of investments in ecosystem management (Sietz *et al.*, 2017). For example, by linking nonlinear ecosystem behaviour to an economic evaluation of land management options, opportunities and challenges have been presented for cost-efficiently restoring or maintaining land ecosystems that are rich in biodiversity and help to mitigate climate change. Additionally, adapting to detrimental changes will require an understanding of how ecological change affects socioeconomic conditions, and effective ways that people in specific contexts can cope with changes, such as modifying growing seasons in response to climate change, or understanding how environmental change affects the ability of indigenous groups to harvest in traditional manners (Savo *et al.*, 2016).

Inherent and systemic uncertainties (time lags, tipping points, interacting mechanisms of change) imply that management can benefit from an adaptive process, whereby learning from ongoing management actions reduce uncertainty and refine management goals (Armitage *et al.*, 2009; Walters, 1986). The "learning by doing" approach of adaptive management is effective in many instances as a operational strategy to managing under uncertainty.

Biggs *et al.* (2012) offer a set of general recommendations for building resilience of ecosystem services, including maintaining diversity and redundancy in both ecological and governance aspects; understanding and managing connectivity, recognizing that there may also be negative effects like disease; managing feedback mechanisms and 'slow' variables important to nature's contributions to people, including monitoring and adaptive management; accounting for complexity in scenarios and planning, including nonlinearity and critical thresholds; promoting learning, participation, and polycentric governance; and enabling the self-organization of agents of change.

5.4.2.5 Rule of law and implementation of environmental policies

Strengthening the rule of law is a vital prerequisite to reducing biodiversity loss and protecting human and ecosystem health (and thus the interests of the public and future generations from incursion by private interests). Stronger international laws, constitutions, and domestic environmental law and policy frameworks, as well as improved implementation and enforcement of existing ones, are necessary to protect nature and its contributions to people. Respecting differences in context, much can be learned from legislation, policies, and instruments with demonstrated successes, while still maintaining opportunities for regulatory experimentation and innovation.

Background

Over the past fifty years, every nation in the world has ratified international environmental laws, passed environmental laws, and developed environmental policies (see for instance chapters 3 and 6). In some countries, these rules have contributed to substantial progress on particular issues. In other countries, these rules have had little or no discernible effect. Despite a proliferation of both international and domestic environmental laws, global environmental problems, including biodiversity loss, climate change, and the breaching of planetary boundaries, continue to worsen.

Evidence

Good governance, respect for the rule of law, and reducing corruption are prerequisites to sustainable development (Morita & Zaelke, 2005). There is a strong correlation between a country's performance on the Rule of Law Index (World Justice Project, 2016) and the Environmental Performance Index (Yale Center for Environmental Law and Policy *et al.*, 2016). For example, the top ten countries in the Rule of Law Index have an average ranking on the EPI of 14.6, while the bottom ten countries in the Rule of Law Index have an average EPI ranking of 126.5 (World Justice Project, 2016; Yale Center for Environmental Law and Policy *et al.*, 2016). From tackling illegal logging to implementing biodiversity laws, strengthening the rule of law is essential (Schmitz, 2016; Wang & McBeath, 2017).

It is widely acknowledged that international agreements intended to protect the planet's ozone layer, beginning with the Vienna Convention for the Protection of the Ozone Layer in 1985, have succeeded in addressing this threat to biodiversity (Fabian & Dameris, 2014). However, international treaties on biodiversity and climate change, while contributing to progress in some areas, have fallen short of achieving their objectives (Kim & Mackey, 2014; Le Prestre, 2017; Rosen, 2015).

Constitutional protections for nature, biodiversity, and endangered species have contributed to conservation successes (Boyd, 2011; Daly & May, 2016; Jeffords & Minkler, 2016). Specific examples include Brazil's extensive constitutional environmental provisions (Mattei & Boratti, 2017), Bhutan's requirement that 60 per cent of forests be protected (Bruggeman *et al.*, 2016), and Ecuador's recognition of the rights of nature (Kauffman & Martin, 2017).

Strong laws intended to protect endangered species (e.g., US Endangered Species Act, Costa Rica's Biodiversity Act) have the potential to not only stem the decline of individual species but also achieve their recovery to healthy population levels (Suckling *et al.*, 2012). Weaker laws (e.g., Canada's Species at Risk Act, Australia's Environment Protection and Biodiversity Conservation Act), less rigorously implemented and enforced, are less likely to achieve recovery goals (Hutchings *et al.*, 2016; McDonald *et al.*, 2015; Mooers *et al.*, 2010; Waples *et al.*, 2013). Policies and programs also have an important complementary role in protecting biodiversity, from monitoring and evaluating wildlife populations to conservation agreements with landowners.

Effective management of human activities within protected areas is also vital to conserving biological diversity (Watson *et al.*, 2014). This applies to the regulation of both legal activities (e.g. ecotourism, recreation) and illegal activities (e.g. poaching, industrial resource exploitation).

Possible points of action

The many scenarios evaluated here recognize that, over the long-term, transformation involves legislations (and incentives) that nurture a shift from linear to circular economies (that is from pathways by which resources are extracted, manufactured into goods, then lost as waste to circular ones based on natural systems that recycle, re-use, and re-create with no waste). This is crucial for several leverage points (5.4.1.2, 5.4.1.6, 5.4.1.7). Innovative legislation and policies approaches to fostering circular economies are appearing in places as diverse as Ontario, the EU, Japan, and China (Ghisellini *et al.*, 2016). These regulatory tools would of course include laws and policies that support the shift from fossil fuels to renewable energy (Fischer & Fox, 2012; Jaffe *et al.*, 2005; Raymond, 2016).

Constitutions have particular force, and their possible amendments can help convey that governments, businesses, and individuals have a responsibility to protect and conserve biodiversity, and that individuals have the right to live in a healthy and ecologically balanced environment (Boyd, 2011). We are also increasingly learning from the experiences at various scales of governance (from municipal to international) that are recognizing the rights of nature, as in Bolivia and New Zealand, and many municipalities elsewhere (Boyd, 2018).

Equally important, however, is addressing corruption in all countries, especially that directly related to the unsustainable use of natural resources. In some regions, curbing corruption alone could have significant positive impact for biodiversity (Stacey, 2018), particularly in countries that are home to biodiversity hotspots, have weak government presence, or are experiencing expansion of commodity production.

5.4.3 Putting It Together: Joint Action of Levers on Leverage Points

Although these various actions and changes may seem insurmountable when approached separately, one action may remove barriers associated with another, potentially having mutually reinforcing positive effects. Accordingly, and perhaps counterintuitively, multiple actions may be successfully undertaken more easily than individual actions, as illustrated by a series of case studies.

5.4.3.1 The Whole Is Easier than the Sum of Its Parts: Six Case Studies

Namibia, Sweden, Costa Rica, the US, the Seychelles, and New Zealand are among the countries that have successfully integrated multiple approaches in protecting biodiversity and ecosystem services. To be clear, these are only specific examples of innovative leadership to illustrate the importance of addressing multiple components and drivers affecting nature and people. There are also important examples of regulatory interventions operating at other scales and in different manners. For example, regional initiatives can have important effects, including via market-based initiatives that affect investment and industrial production by putting a price on pollution, particularly when framed around positive values of collective benefit (Raymond, 2016). Similarly, there are countless examples of local initiatives that have proven effective, from bylaws restricting pesticide use for cosmetic purposes to bans on plastic bags and other single-use plastic items.

Namibia's success with community-based conservation illustrates many of the above levers and how they can work together. Following independence from South Africa in 1990, Namibia's new government passed progressive legislation in 1996 that devolved user rights regarding nature (in particular wildlife) to local communities (5.4.2.5, Law; 5.4.1.5, Involving local communities).

This change in governance allowed communities to register their traditional lands as conservancies, providing them with both the legal right and the legal responsibility to manage their customary landholdings for the sustainable flow of benefits from wildlife and other natural resources. The proliferation of conservancies—from 4 in 1998 to 83 at present—has resulted in increased levels of financial benefits to the rural poor (Jones *et al.*, 2012; Naidoo *et al.*, 2016), recovering populations of wildlife (Naidoo *et al.*, 2011), a tremendous increase in the amount of land under conservation management (MET/NACSO, 2018), and the reconnection of a link between Indigenous Peoples and wildlife that spans thousands of years of joint history (5.4.1.2, Visions of a good quality of life). Governance decisions were the overall platform for the conservation successes that followed, with subsequent innovative linkages between local communities and international markets for tourism and plant products providing the tangible mechanisms by which local people have benefited from their natural resources (5.4.1.7, Technology and innovation; Barnes *et al.*, 2002). While community-based conservation has helped take a step towards improving the dramatic inequality between the marginalized rural poor and wealthier ranchers and urbanites in Namibia (5.4.1.4, Inequalities), considerable threats nevertheless remain that could hamper further gains. These include increased levels of human-wildlife conflict (Kahler & Gore, 2015), incentive structures (5.4.2.1) that are preventing the full sociocultural, economic, or biophysical values of wildlife from being unlocked (e.g., subsidies and political power dynamics related to livestock and mineral extraction; Muntifering *et al.*, 2017) and competing demands for land that are not evaluated in a synthetic way by governments at various levels of responsibility (5.4.2.2, Integrated management/governance). Nevertheless, the successes seen in Namibia demonstrate that conservation by local communities on their lands can lead to gains both for people and for wildlife.

Sweden has been a global leader on issues ranging from climate change to toxic substances, ranked fifth on the Yale Environmental Performance Index in 2018 (Yale Center for Environmental Law and Policy (YCELP) *et al.*, 2018), and is proactively discussing what a future without economic growth would look like (Boyd, 2015). In 1999, the Swedish Environmental Code established a goal of solving all of the country's environmental problems over the course of a single generation (Government of Sweden, 2000). Sweden has recalibrated its economy by imposing taxes on pollution, pesticides, and waste to reduce levels of these undesired items (5.4.2.1, Incentives and subsidies; 5.4.1.3, Behaviour change) (Wossink & Feitshans, 2000). Sweden has reduced sulphur dioxide emissions by ninety per cent (in part due to a tax on emissions), cut greenhouse gas emissions by more than 20 per cent since 1990 (in part due to a high carbon tax), contributing to improved quality of life (cleaner air, safer streets, better public transit, healthier people, and more comfortable buildings). Sweden's long-term goal is to be fossil fuel free by 2050. They were the first country in the world to take strong regulatory action on polybrominated diphenyl esters (PBDEs) after researchers discovered rapidly rising levels of these flame retardant chemicals in women's breast milk (5.4.2.3, Early or precautionary action) (Darnerud *et al.*, 2015). Sweden has created timelines for eliminating the use of a broad range of toxic substances including mercury, lead, carcinogens, and chemicals that harm reproduction (5.4.2.3) (Swedish Environmental Protection Agency, 2005). They consistently rank as one of the most generous countries in the world, dedicating one per cent of their annual GDP as Official Development Assistance to help the world's poorest nations (5.4.1.4, Inequalities) (OECD, 2018). This is more than three times the level of foreign aid provided by Canadian and American governments.

Recently, Sweden recognized that some of their environmental solutions actually exported problems to other countries (i.e., leakage or spillover impacts) (Swedish Environmental Protection Agency, 2011). For example, reduced levels of logging in Swedish forests were offset by rising lumber and paper imports from countries with more biodiverse forests. Declining oil use was achieved, in part, through rising imports of biofuels from Brazil, with adverse effects on tropical forests. Sweden now recognizes that today's levels of consumption in wealthy countries need to be reduced to alleviate pressure on overexploited planetary ecosystems (5.4.1.2, Consumption) (Swedish Environmental Protection Agency, 2011). To their credit, Sweden revised its goal of achieving sustainability within one generation to state "the overall goal of environmental policy [is] to hand over to the next generation a society in which the major environmental problems in Sweden have been solved, *and this should be done without increasing environmental and health problems outside Sweden's borders*" (5.4.1.6, Telecoupling; 5.4.2.5, Law) (Swedish Environmental Protection Agency, 2013). To achieve this goal, the Swedish government observed that "policy instruments and measures must be designed in such a way that Sweden does not export environmental problems" but rather solves them through changing patterns of production and consumption (5.4.1.2, Consumption; 5.4.1.6, Telecoupling) (Swedish Environmental Protection Agency, 2011).

Costa Rica is widely recognized as an environmental leader, as a result of decades of determined effort including the key turning point of constitutional recognition of the right to a healthy environment in 1994 (5.4.2.5, Law; 5.4.1.5, Human rights and Indigenous peoples' participation) (Boyd, 2011). This small Latin American nation has enacted and implemented strong laws (such as the award-winning Law on Biodiversity, which recognizes nature's intrinsic value), placed more than one quarter of its land in parks and protected areas, and reversed the trend of deforestation (5.4.2.5, Law) (Hanry-knop, 2017). Impressively, Costa

Rica produces 99% of its electricity from renewable energy sources including hydroelectricity, geothermal, wind, and solar (5.4.2.4, Managing for resilience; 5.4.1.7, Technology and innovation) (Hanry-knop, 2017). Costa Rican laws prohibit open pit mining and offshore oil and gas development (5.4.2.5, Law). The country has a national carbon tax whose revenues are dedicated to helping small-scale farmers in reforestation and habitat protection (5.4.2.1, Incentives and subsidies). This national payment for ecosystem services program that has been shown to leverage existing inherent motivations for conservation (5.4.1.3, Enlisting values) (Kosoy *et al.*, 2007).

In 1948, Costa Rica decided to disband its military and invest the money saved in education and health care (5.4.1.2, Visions of a good quality of life; 5.4.1.8, Education) (Abarca & Ramirez, 2018). The country now enjoys high levels of literacy (97.4 per cent) and long life expectancy (79.6 years) (UNDESA, 2017; UNESCO, 2018). Twenty years ago, Costa Rica's leading exports were coffee and bananas. Today Costa Rica's most valuable exports are computer chips and medical prosthetics, as corporations have located manufacturing facilities to take advantage of the country's educated workforce, clean air, and clean water. Costa Rica is the top-ranked country in the world on the Happy Planet Index, which integrates measures of life expectancy, self-rated happiness, and per capita ecological footprints (HPI, 2016). The national expression "pura vida" or the pure life, refers to achieving happiness in harmony with nature, a goal also established in the 2009 constitution of Ecuador (5.4.1.2, Visions of a good quality of life).

The effectiveness of strong legal protection for biodiversity is illustrated by the United States, which initially passed a law to protect endangered species in 1967, revised it in 1969, and introduced its most powerful elements, which remain in place today, in 1973 (5.4.2.5, Law) (Boyd, 2018). The law compelled the United States to host an international meeting intended to spark the development of a treaty to protect endangered species. The meeting led to the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES). In a lawsuit involving the construction of a dam that threatened and endangered fish called the snail darter, the US Supreme Court ruled that "The plain intent of Congress in enacting the *Endangered Species Act* was to halt and reverse the trend toward species extinction, whatever the cost" (5.4.2.5; U.S. Supreme Court, 1978). The law's bold regulatory power was also alienating to some landowners, however, who resented the state imposition of restrictions on individuals and firms who happened to host species at risk. Arguably, the Act's survival in Congress and its ability to garner the willing participation of landowners depended upon regulatory innovation that removed disincentives for reporting species at risk and provided incentives for protection and restoration (5.4.1.3 Values, agency; 5.4.2.1 Incentives) through the Safe Harbour Agreement and mitigation banking (Bonnie, 1999; Fox *et al.*, 2006; Fox & Nino-Murcia, 2005). These programs enabled landowners to act in accordance with pre-existing stewardship values (5.4.1.3, Values) (Wilcove & Lee, 2004).

More than 30 species have been removed from the US endangered species list because their populations have recovered, including the bald eagle, peregrine falcon, gray whale, grizzly bear, gray wolf, brown pelican, Steller sea lion, American alligator, a snake, a flycatcher, a flying squirrel, a lizard, an orchid, and a daisy (U.S. Fish & Wildlife Service, 2018). Bald eagle populations in the lower 48 states rebounded from a low of roughly 400 nesting pairs in the early 1960s to more than 10,000 today. Keys to the bald eagle's recovery include prohibitions on hunting, banning the pesticide DDT, and protecting critical habitat, such as nesting sites (5.4.2.5, Law) (Doub, 2013). The US Center for Biological Diversity identified more than 20 species whose populations increased by more than 1,000 per cent in recent decades (Suckling *et al.*, 2012). There was a 2,206% increase in nesting Atlantic green sea turtle females on Florida beaches. The California least tern enjoyed a 2,819% increase in nesting pairs. The San Miguel island fox population increased 3,830%. Numbers of the El Segundo blue butterfly increased 22,312%. Studies indicate that roughly 90% of species listed under the US Endangered Species Act are on track to meet their recovery targets by the projected deadline (Suckling *et al.*, 2012).

The Seychelles is among the world's leaders in the percentage of its land that is designated as protected, at over 42 per cent (World Bank, 2018). The Seychelles Islands amended their constitution in 1993 to recognize that citizens have the right to live in a healthy environment, and that government has a responsibility to protect the environment (5.4.2.5, Law; 5.4.1.5, Human rights) (Boyd, 2011). In a case involving the prosecution of eight individuals for unlawful possession of meat from protected species, including sea turtles and boobies, the Supreme Court of Seychelles referred to the constitutional right in interpreting the *Wild Animals and Birds Protection Act*. The court wrote: "The right to a healthy environment has become a fundamental right. In Seychelles that right extends to the Management of Marine Resources as well as protected Land or Sea Birds" (5.4.2.5, Law) (Seychelles Legal Information Institute, 2004). Seychelles was recognized by the United Nations Environment Program as a Center for Excellence in its approach towards coastal development with reference to both efforts to protect coral reefs and a successful dolphin-free tuna industry (5.4.2.2, Integrated management; 5.4.2.4, Managing for resilience) (CountryWatch, 2018). Finally, air quality in the Seychelles is ranked number one according to the Yale Environmental Performance Index (Yale Center for Environmental Law and Policy *et al.*, 2016).

New Zealand is the highest rated non-European country on the EPI, ranked 17th in 2018 (Yale Center for Environmental Law and Policy (YCELP) *et al.*, 2018). More than 32 per cent of New Zealand's land enjoys legal protection (World Bank, 2018). New Zealand is the first country in the world to pass laws that transfer ownership of land from humans to nature (5.4.2.5, Law; 5.4.1.5, Human rights and conservation) (Boyd, 2018). Two recent laws, governing the Whanganui River and an area previously designated as Te Urewera National Park, designate these natural systems as legal persons with specific rights (New Zealand Government, 2017). For example, the Te Urewera ecosystem has the right to protection of its biological diversity, ecological integrity, and cultural heritage in perpetuity (Te Urewera Act, s. 4). These innovative laws that may eventually change the way New Zealanders relate to nature, from one in which we treat nature as a commodity that we own, towards nature as a community to which we belong (5.4.1.3, Behaviour change; 5.4.2.4, Managing for resilience). In each case, the laws establish a guardian, comprised of Indigenous Maori representatives and government representatives, to ensure that nature's rights are respected and protected (5.4.1.2, Visions of a good quality of life) (Te Urewera Act, ss. 16-17). All persons exercising powers under the Te Urewera Act "must act so that, as far as possible,

(a) Te Urewera is preserved in its natural state:
(b) the indigenous ecological systems and biodiversity of Te Urewera are preserved, and introduced plants and animals are exterminated" (Te Urewera Act, s. 5)

New Zealand is also noteworthy for having changed its electoral system in 1992 from first-past-the-post to mixed-member proportional representation (5.4.2.4, Managing for resilience) (New Zealand Electoral Commission, 2014). Advantages of proportional representation include parliaments that fairly reflect the popular vote, embody diverse populations, and require a genuine majority of the votes to form a majority government. The Green Party has played a significant role in New Zealand politics since the shift to proportional representation, serving in several coalition governments and contributing to stronger environmental laws and policies (Bale & Bergman, 2006).

5.4.3.2 Initiating Transformation, before Political Will

The examples provided throughout the chapter largely illustrate the multifaceted progress that is possible given sufficient political will, which begs the question of how to initiate transformative change towards sustainable pathways in the absence of such political will. Even in the six cases above (5.4.3.1), surely the political opportunity was created in part by various actors intervening in creative ways to enable broad and focused public support (such reconstructions of historic political processes are beyond the scope of this assessment). One of the most empowering findings that emerge from the analysis of societal responses to nature and biodiversity degradation is that individual and local efforts might be scaled up to transformative change for sustainability, including as initiated by the private sector, civil society, and governments at all scales.

There are countless worthy initiatives addressing the aforementioned leverage points and levers in various ways. These efforts deserve to be commended, and they can scale up. But they can also be better aligned with our findings above (5.4.1, 5.4.2). For example, there is a great deal of attention to reforming investment and technological innovation for a low-carbon economy, but few efforts broaden beyond climate pollution to include comprehensive impacts on biodiversity and ecosystem services, as suggested above (5.4.1.6, 5.4.1.7). Addressing the leverage points obliquely or partially (e.g., only carbon) can be counterproductive, e.g., potentially incentivizing other kinds of impacts on nature.

Existing efforts can also be better integrated, so that the various efforts can together leverage sustainability rather than undercut each other. For example, efforts to change behaviours among producers or urban populations (5.4.1.3) can be designed also to support the involvement of Indigenous Peoples and Local Communities (rather than detracting or distracting from this; 5.4.1.5).

There are also three apparent gaps in current efforts. First is laying the groundwork for a broad-scale reform of subsidies and incentives, which have structural effects (5.4.2.1). Although there is recent progress with carbon pricing (Kossoy *et al.*, 2015), there are benefits to extending these efforts in several ways. These would include advocating for and ensuring that carbon prices permeate supply chains and cross-border trade (Fischer & Fox, 2012); extending beyond carbon to include water (Molle & Berkoff, 2007), land use or conversion, and other metrics of damage or threat to biodiversity and ecosystem services; and ensuring that incentive programs are designed to foster relational values, not just 'buy' behaviour change (Chan *et al.*, 2017a) (5.4.2.1). Moreover, across many nations, there is disproportionately little effort to take stock of and address the perverse ecological impacts of subsidies on production and consumption (5.4.2.1). Because of the opposition that often arises in response to such policy reform, however, in many contexts policy progress may rely upon first laying the groundwork by enabling the widespread expression and reinforcement of supporting values (5.4.1.3; see also final point).

Second, compared with environmental laws and policies, there is a dearth of attention to the structure and approach of governing institutions to ensure that they are adaptive, precautionary, and addressing the resilience of social-ecological systems (5.4.2.2, 5.4.2.3, 5.4.2.4). Multi-stakeholder non-governmental organizations—often around certification systems—offer some promise to leverage change within commodity sectors (e.g., palm oil, soy, cotton, and rubber), when power inequities are addressed (e.g., so that small-holders have a substantial voice). Such structural changes can be fundamental (e.g., Olsson *et al.*, 2008), and yet sometimes they can elicit a broader base of support or less focused opposition. Accordingly, they may present especially promising targets for advocacy and intervention, recognizing it may take persistent and prolonged engagement.

Finally, although there are many behaviour-change programs, these efforts generally encounter one of two major obstacles to fostering system transformation. Many campaigns appeal only to a small minority of self-identified environmentalists (Moisander, 2007), which can impede behaviour change among the broader public due to negative stereotypes and the narrow reach of social norms (Chan *et al.*, 2017b). Alternatively, broad systems of taxation or incentives often lack a broad base of support or conflict with existing attitudes and values, which can backfire due to widespread resentment and/or non-participation (Chan *et al.*, 2017a). The values and concerns of voting publics are often key impediments to and enablers of top-down change. Accordingly, we see a crucial opportunity in programs and approaches that seek to leverage widely held but latent values of responsibility into new social norms in environmental (and social-ecological) contexts, perhaps by empowering all people to act in accordance with those values—easily, enjoyably and inexpensively (5.4.1.3).

Thus, a key message of this chapter is the transformative potential of identifying the diverse relational values that people already hold (principles, preferences, and virtues about relationships involving nature) that are conducive to sustainability and engineering the structural and social changes that will allow the full expression and growth of those values. These values include diverse ideals of sufficiency at the centre of *notions of a good life* that don't entail runaway *consumption* (5.4.1.1, 5.4.1.2); diverse values of responsibility are central to enabling new *social norms and action* for sustainability (5.4.1.3) including through *incentives* and regimes of *innovation, technology and investment* that align with those values (5.4.2.1, 5.4.1.7); recognition of local values consistent with conservation is an important reason to *involve Indigenous Peoples and Local Communities in conservation* (5.4.1.5); *education* is key for appreciating diverse values, which are embodied in the diverse *knowledge systems* that deserve to be maintained (5.4.1.8).

5.5 CONCLUDING REMARKS

Options for sustainable pathways abound, and our analysis suggests that they are within reach, if a diverse set of actors take action to enable them. These pathways entail addressing knotty nexuses of competing human needs, including food, biodiversity conservation, freshwater, oceans and coasts, cities, and energy. Both the actions and the pathways are clearly context-specific, with a need to tailor to regional and local circumstances via inclusive participation, but there are also key commonalities across regions and nexus points.

Across and beyond the six foci, one commonality is a diverse set of 'levers' and leverage points within which outcomes for nature, its contributions to people, and human drivers can be accomplished with strategic change. Many of these levers and leverage points have been identified elsewhere, but none have been employed widely and fully. This limited uptake is, of course, due to a variety of obstacles (chapter 6), but none of these are insurmountable with time, effort, resources, coordination, creativity, strategy, and persistence.

While all levers and leverage points are important, not all need be addressed by any one project, policy, or actor. But given strong interactions (e.g., synergies and trade-offs) between various levers and leverage points, we have described how engaging several together may be easier and more effective than addressing them piecemeal (5.4.3). For example, subsidy reform (5.4.2.1) and improved policies for innovation and technology (5.4.1.7) are excellent steps alone but often ineffectual in the presence of systemic corruption or weak rule of law (5.4.2.5). Similarly, enlisting values to encourage widespread conservation (5.4.1.3) and involving Indigenous Peoples and Local Communities in landscape management (5.4.1.5) are much needed, but they cannot yield long-term achievement of nature-based goals without also reining in overconsumption (5.4.1.2), likely by engaging appropriate visions of a good quality of life (5.4.1.1).

A key constituent and outcome of the transformational pathways suggested to achieve the SDGs is the emergence of a global sustainable economy, underpinned by a networked set of sustainable societies. The SDGs and many other agreements and collective efforts are inspiring societies and nations to envision a world in which innovation, new technology, and environmentally responsible consumption evolve towards eliminating environmental impacts, diminishing inequalities, and improving human well-being. Such a world would be enabled by diverse people and organizations engaging voluntarily in conservation and restoration, where all people are accorded inherent rights to nature and celebrated for their crucial roles in maintaining that nature for distant people, future generations, and nature itself.

CHAPTER **6**

OPTIONS FOR DECISION MAKERS

EXECUTIVE SUMMARY

1 The Sustainable Development Goals and the 2050 Vision for Biodiversity cannot be achieved without transformative change, the conditions for which can be put in place now *(well established)* {6.2; chapters 2, 3, 5}*.* In the short term (before 2030), all decision makers can contribute to the sustainability transformation, including through the rapid and improved deployment of existing policy instruments and new initiatives that more effectively enlist individual and collective action for transformative change, and the reform and removal of harmful existing policies and subsidies *(well established)*. Additional measures are necessary to enable transformative change in the long term (up to 2050) to address the indirect drivers that are the root causes of nature deterioration (*well established*), including changes in social, economic and technological structures within and across nations {6.2, 6.3, 6.4}.

2 Transformative change needs innovative approaches to governance. Such transformative governance can incorporate different existing approaches, such as integrative, inclusive, informed and adaptive governance. While these governance approaches have been extensively practiced and studied separately, their combined contribution to enabling transformative change has not yet been thoroughly explored (*established but incomplete)* {6.2}. Integrative approaches, such as mainstreaming across government sectors, are focused on the relationships between sectors and policies and help to ensure policy coherence and effectiveness (*well established*). Inclusive approaches help to reflect a plurality of values and ensure equity (*established but incomplete*), including through equitable sharing of benefits arising from their use and rights-based approaches (*established but incomplete*). Informed governance entails novel strategies for knowledge production and co-production that are inclusive of diverse values and knowledge systems (*established but incomplete*). Adaptive approaches, including learning from experience, monitoring and feedback loops, contribute to preparing for and managing the inevitable uncertainties and complexities associated with social and environmental changes (*established but incomplete*) {6.2}.

3 Empowering all actors can promote sustainability and ensure inclusiveness and equity. Current policies and actions for nature, nature's contributions to people (NCP) and good quality of life (GQL) often privilege elite actors and their value systems, which hampers their legitimacy and effectiveness *(well established)*. Empowerment strategies can be implemented by governments and civil society groups, and include education and information instruments, but also redistribution of power and rights so that all can assume responsibility and control over their lives and futures *(well established)*. Existing approaches such as co-management and community-based natural resource management can be effective in ensuring the equal distribution of the costs and benefits of conservation and reconciling different interests and values, provided that they recognize and address trade-offs and uneven power relations *(well established)*. Inclusiveness and equity will imply recognizing the inevitability of hard choices, costs and common responsibilities *(well established)* {6.2; 6.3; 6.4}.

4 Effective decision making for transformative change uses a mix of instruments and tools, and bridges across different sectors, levels and scales *(established but incomplete).* Since no single instrument or tool is sufficient *(well established)*, policy mixes need to be carefully tailored to – together – effectively address all direct and indirect drivers of nature deterioration **(Table 6.1)**. Sectoral policies and measures can be effective in particular contexts, but often fail to account for indirect, distant and cumulative impacts, which can have adverse effects, including exacerbating inequalities *(well established).* Cross-sectoral approaches, including landscape approaches, integrated watershed and coastal zone management, marine spatial planning, bioregional scale planning for energy and new urban planning paradigms, offer opportunities to reconcile multiple interests, values and forms of resource use, provided that these cross-sectoral approaches recognize trade-offs and uneven power relations between stakeholders (*established but incomplete*) {6.3; 6.4}.

5 Since the effectiveness of alternative actions and policies depends on the decision context, there are no generic recipes for success *(established but*

incomplete). All decision makers can contribute to enhancing the effectiveness of instruments in specific contexts over time through informed and adaptive governance approaches. The comprehensive review of the application of policy instruments presented in this chapter indicates that the implementation of many existing instruments (e.g. protected areas) can be further enhanced, while on the other hand the effectiveness and application of other instruments (e.g. information campaigns for consumers or agricultural certification schemes) requires more research. Since the effectiveness of many instruments for the conservation of nature and its contributions in different contexts is currently unknown, more research and appropriate monitoring is needed {6.3; 6.4}.

6 **Decision makers have a range of options and tools for improving the sustainability of economic and financial systems *(well established)* {6.4}. Achieving a sustainable economy involves making fundamental reforms to economic and financial systems and tackling poverty and inequality as vital parts of sustainability** *(well established)* {6.4}. Governments could reform subsidies and taxes to support nature and its contributions to people, removing perverse incentives, and instead promoting diverse instruments such as payments linked to social and environmental metrics, as appropriate *(established but incomplete)* {6.4.1}. Trade agreements and derivatives markets could be reformed to promote equity and prevent deterioration of nature, although there are uncertainties associated with implementation (*established but incomplete*) {6.4.4}. To address overconsumption, voluntary measures can be more effective when combined with additional incentives and regulation, including promotion of circular economies and sustainable production models *(well established)* {6.4.2; 6.4.3}. Although market-based policy instruments such as payments for ecosystem services, voluntary certification and biodiversity offsetting have increased in use, their effectiveness is mixed, and they are often contested; thus, they should be designed and applied carefully to avoid perverse effects in context (*established but incomplete*) {6.3.2.2; 6.3.2.5; 6.3.6.3}. Alternative models and measures of economic welfare (such as inclusive wealth accounting, natural capital accounting and degrowth models) are increasingly considered as possible approaches to balancing economic growth and conservation of nature and its contributions and recognizing trade-offs, value pluralism and long-term goals *(established but incomplete)* {6.4.5}.

7 **Recognizing the knowledge, innovations and practices, institutions and values of Indigenous Peoples and Local Communities and their inclusion and participation in environmental governance often enhances their quality of life, as well as nature conservation, restoration and sustainable use, which is relevant to broader society *(well established)* {6.2.4.4}. Governance, including customary institutions and management systems, and co-management regimes involving Indigenous Peoples and Local Communities, can be an effective way to safeguard nature and its contributions to people, incorporating locally attuned management systems and indigenous and local knowledge.** The positive contributions of Indigenous Peoples and Local Communities to sustainability can be facilitated through national recognition for land tenure, access and resource rights in accordance with national legislation{6.3.2.3}, the application of free, prior and informed consent {6.3.6}, increasing participation in resource management decision-making (including through capacity development and financial support) {6.2.4.4, 6.3.4}, and improved collaboration, fair and equitable sharing of benefits arising from the use, and co-management arrangements with Indigenous Peoples and Local Communities *(well established)* {6.2.4, 6.3.2.3}.

8 **Multi-functional landscapes consisting of mixed land systems that include intensive and extensive forms of land use are critical for food security and rural livelihoods, generate a diversity of nature's contributions to people, and can harbour considerable biodiversity (*well-established)* {6.3.2}.** At the same time, these landscapes are the space where the largest conflicts with nature take place *(well established).* Policy mixes harmonized across sectors, levels of governance and jurisdictions can account for ecological and social differences across and beyond the landscape, build on existing forms of knowledge and governance and address trade-offs between tangible and non-tangible benefits in a transparent and equitable manner *(established but incomplete).* Options for the private sector – especially local land managers – include diversified land uses and crops, including agroforestry practices, crop rotations, maintenance of semi-natural habitats, soil conservation practices and habitat restoration activities *(well established)*. Options that require the engagement of all actors related to the landscape (e.g., regional governments, producers, neighboring urban inhabitants, protected area authorities) include context-sensitive combinations of participatory approaches to resolve trade-offs and conflicts among objectives, certification schemes for landscape products, direct payments such agri-environmental schemes and PES, research on ecological intensification practices, technical outreach and information campaigns *(established but incomplete)* {6.3.2}.

9 **Feeding the world in a sustainable manner, especially in the context of climate change and population growth, entails food systems that ensure adaptive capacity, minimize environmental impacts, eliminate hunger, and contribute to human health and animal welfare *(established but incomplete)* {6.3.2.1}.** Ensuring the adaptive capacity of food production

incorporates measures that conserve the diversity of genes, varieties, cultivars, breeds, landraces and species. Essentially, this refers to further improvement and harmonization of present global mechanisms of genetic material transfers (e.g., the Nagoya Protocol, the International Treaty on Plant Genetic Resources for Food and Agriculture and the International Convention for the Protection of New Varieties of Plants*) (well established).* Options for the private sector – especially food producers – include expanding and enhancing sustainable intensification, engaging in ecological intensification and sustainable use of multi-functional landscapes, increasing focus on climate-resilient agriculture, and improving food distribution *(established but incomplete).* Options for governments at the international and national levels include regulating commodity chains, managing large-scale land acquisitions, and expanding food market transparency and price stability. Options that address and engage other actors in food systems (including the public sector, civil society and consumers, grassroot movements) include participatory on-farm research, promotion of low-impact and healthy diets and localization of food systems. Such options could help reduce food waste, overconsumption, and demand for animal products from unsustainable production, which could have synergistic benefits for human health *(established but incomplete)* {6.3.2.1}.

10 Sustainable forest management can be better achieved through promoting multifunctional, multi-use, multi-stakeholder and improving community-based approaches to forest governance and management (*well established*) {6.3.2.2}. National and subnational governments can further promote and strengthen community-based management and governance, including customary institutions and management systems, and co-management regimes involving Indigenous Peoples and Local Communities with due recognition of their knowledge and rights who manage almost one third of the forests in the Global South; and improve the conservation and sustainable use of (old-growth) forests through a combination of measures and practices, including protected and other conservation areas; sustainable management and reduced impact logging, forest certification, PES and reducing emissions from deforestation and forest degradation (REDD+); supporting reforestation and forest restoration; transparent monitoring; and addressing illegal logging *(established but incomplete).* International agencies can technically and financially support governments and other stakeholders in achieving the above, including through effective implementation of multilateral environmental agreements (MEAs) and other relevant international agreements *(well established).* Decision makers at all levels can also improve forest governance by recognizing different value systems while formulating forest policies and making management decisions and adopting informed and adaptive decision-making practices *(established but incomplete)* {6.2.4.1; 6.3.2.2; 6.3.2.3}.

11 Expanding and effectively managing the current network of protected areas, including terrestrial, freshwater and marine areas, is important for safeguarding biodiversity (*well established*), particularly in the context of climate change. Conservation outcomes also depend on adaptive governance, strong societal engagement, effective and equitable benefit-sharing mechanisms, sustained funding, and monitoring and enforcement of rules *(well established)* {6.3.2.3}. Protected areas support nature, deliver NCP and contribute to good quality life *(well established)*. National Governments play a central role in supporting primary research and effective conservation and sustainable use of multi-functional landscape and seascape. The latter include planning ecologically representative networks of interconnected protected areas to cover key biodiversity areas and managing trade-offs between societal objectives that represent diverse worldviews and multiple values of nature *(established but incomplete)*. Governance diversity, tailored to the local conditions, includes co-management schemes, local empowerment, and formal recognition of IPLCs rights over their territories *(well established).* Large-scale, proactive landscape planning, including transboundary conservation planning, helps prioritize land uses that balance nature, NCP and GQL *(well established)*. Implementation beyond protected areas includes combating wildlife and timber trafficking through effective enforcement and ensuring the legality and sustainability of trade in wildlife. Such actions include prioritizing wildlife trafficking in criminal justice systems, using community-based social marketing to reduce demand and implementing strong measures to combat corruption at all levels (*established but incomplete)* {6.3.2.3}.

12 Managing coastal and near-shore ocean management for sustainable and resilient futures, in the face of economic pressures and climate change, entails applying policy mixes, including integrated coastal planning and restoration, designation and expansion of Marine Protected Areas, control of plastic and other pollution, and reform of fishery subsidy strategies (*established but incomplete*) {6.3.3.3}. Marine protected areas (MPAs) have demonstrated success in both biodiversity conservation and improved local quality of life when managed effectively. MPAs can be further expanded through larger or more interconnected protected areas or new protected areas in currently under-represented regions and key biodiversity areas *(established but incomplete)* {6.3.3.3.1}. The fishing industry, a major source of aquatic biodiversity losses, can be supported by positive incentives and the reform and removal of harmful existing policies and subsidies to change current practices and remove derelict gear that threatens nature *(well established)* {6.3.3.3.2}. Improved surveillance and investment in scientific research are critical due to major pressures on coasts (including development, land reclamation and water pollution), implementing marine conservation outside protected areas, such as integrated coastal planning, is important for biodiversity conservation and sustainable use *(established but incomplete*) {6.3.3.3}. Other measures to expand multi-sectoral cooperation on coastal management include corporate social responsibility measures, standards for building and construction and eco-labelling (*well established*) {6.3.3.3.2, 6.3.3.3.5}. Additional tools could include economic instruments for financing conservation both non-market and market based, including for example payment for ecosystem services, biodiversity offset schemes, blue-carbon sequestration, cap-and-trade programs, green bonds and trust funds and new legal instruments {6.3.3.1.3}.

13 Governance for the oceans and high seas is currently marked by policy fragmentation leading to nature deterioration *(established but incomplete)* {6.3.3.1}. To sustain biodiversity and fisheries in the high seas, existing sectoral regulatory agencies such as shipping authorities and Regional Fisheries Management Organizations can increase the pace of mainstreaming nature into their policies *(well-established)* {6.3.3.2}. Based on the experience of regional fisheries management organisations, a strong science foundation for informed governance is essential for effective protection, although costly in terms of human resources and technology *(well established)* {6.3.3.2.2}. Cost-effectiveness can be achieved through sharing and integrating information systems across agencies and sectors (e.g., shipping, fishing, mining, and port agencies) and through collaboration between industry, governments and non-governmental organizations *(well established*) {6.3.3.1.1}. New legal instruments such as the proposed international legally binding instrument under the United Nations Convention on the Law of the Sea (UNCLOS) on the conservation and sustainable use of marine biodiversity of areas beyond national jurisdiction could accelerate national action to provide nature protection, particularly when combined with strengthened regional cooperation *(established but incomplete)* {6.3.3.3.1, 6.3.3.1.1}.

14 Inclusive water governance can promote informed decisions, facilitate stronger interaction between communities and conservation activities, and foster equity among water users (*well established*) {6.3.4}. Creating a space for stakeholder engagement and transparency in water conservation and transboundary water management can help to minimize environmental, economic and social conflicts as well as risks *(well established)* {6.3.4.3, 6.3.4.7}. Integrated freshwater management depends, *inter alia*, on recognizing the functional interdependencies between and among rural landscape management and urban demands, incorporating a regional view of the water cycle, understanding of conflicting interests for water uses, and assessing the opportunities for cooperation among users *(established but incomplete)* {6.3.4.1, 6.3.4.2, 6.3.4.6}. In the short term, collection and monitoring of data remains crucial to governments and private actors for water abstraction and management due to the interconnected nature of surface and groundwater (*well established)* {6.3.4.1}. With regard to watershed payment for ecosystem services programmes, their effectiveness and efficiency can be enhanced by acknowledging multiple values in their design, implementation and evaluation and setting up impact evaluation systems (*established but incomplete*) {6.3.4.4}. National regulatory frameworks, policy guidance, institutional arrangements, and water quality standards can set benchmarks for better performance and attract investment to improve water resources and conditions *(well established)* {6.3.4.5, 6.3.4.6}.

15 Nature-based solutions can be cost-effective for meeting the Sustainable Development Goals in cities, which are crucial for global sustainability *(established but incomplete)* {6.3.5}. Integrated urban planning can play a significant role in reducing the environmental impacts of cities and the transformation to sustainability *(well established)* {6.3.5.1, 6.3.5.3}. Nature-based approaches include safeguarding or retrofitting of green and blue infrastructure such as green spaces, water, and vegetation and tree cover into existing urban areas and in new settlements. They can contribute to flood protection, temperature regulation, urban food production, recreation, cleaning of air and water, treating wastewater and the provision of energy, locally sourced food and the health benefits of interacting with nature. They can also enhance urban biodiversity, and they can provide cost effective solutions for local climate change adaptation and promoting low carbon cities *(well established)* {6.3.5.2}. Nature-based solutions and integrated planning also enable improved access to social services, such as sanitation and housing *(well established)* {6.3.5.4}.

16 Recognizing pluralistic values and diverse interests are key to mitigating the impacts, and enabling the sustainable management of energy, mining and infrastructure *(established but incomplete)* {6.3.6}. At all levels of governance, it is crucial to integrate sustainability criteria and internalize the impacts of bioenergy projects on nature *(established but incomplete)* {6.3.6.1}. Promoting innovative financing and ensuring compensation for environmental and social impacts of energy, mining and infrastructure projects are important measures in the sustainable energy transition and responsible mining *(established but incomplete)* {6.3.6.2, 6.3.6.3, 6.3.4.6}. Community-based management and respect for the rights of Indigenous Peoples and Local Communities to land and water has emerged as a way to ensure access to clean, reliable and affordable energy *(well established)* {6.3.6.4, 6.3.6.5}. Incentive programs and policies can also aim at reducing consumption, improving energy efficiency, and supporting community-based management and decentralized sustainable energy production {6.3.6.1,6.3.6.3, 6.3.6.4,6.3.6.5}.

Table 6 1 Main options for decision makers: Instruments that can be included in smart policy mixes.

Decision maker	Instruments that can be included in smart policy mixes within or across issues {Tables 6.3, 6.4, 6.5, 6.6,			
	Landscape approaches	**Food**	**Forest**	**Conservation**
Intergovernmental organizations	Support and facilitate the development of transformative landscape governance networks together that develop policy mixes for sustainable use of multi-functional landscapes	Support and facilitate expansion and enhancement of sustainable intensification, ecological intensification and sustainable use of multi-functional landscapes Develop and harmonize agreements on genetic resources for agriculture	Improve reducing emissions from deforestation and forest degradation (REDD+) and payment for ecosystem services (PES) policies Address illegal logging and trade in illegal timber Facilitate enhanced forest monitoring	Facilitate expansion and improved management, functionality and connectivity of (transboundary) protected areas Address illegal wildlife trade Facilitate enhanced implementation of and coordination between multilateral environmental agreements Promote mainstreaming of biodiversity into other sectors Enable more financial support for conservation
Governments (national, subnational, local)	Support, facilitate and engage in transformative landscape governance networks	Encourage dietary transitions and alternate consumption Support and facilitate expansion and enhancement of sustainable intensification; ecological intensification and sustainable use of multi-functional landscapes Facilitate localization of food systems and reduction of food waste Facilitate improvement certification standards Enable conservation of genetic resources for agriculture Manage large-scale land acquisitions	Improve the conservation of (old-growth) forests Enable expansion and improvement of community-based forest management and co-management Improve REDD+ and payment for ecosystem services policies Support reduced impact logging Promote improvement and implementation of certification Support reforestation and forest restoration Address illegal logging and trade in illegal timber Enhance forest monitoring	Expand and improve management, functionality and connectivity of (transboundary) protected areas Recognize management by IPLCs and Other Effective area-based Conservation Measures Strengthen enforcement and implementation of law and multilateral environmental agreements (MEA) and address corruption Enforce free, prior and informed consent (FPIC) and recognize IPLC rights Enhance approaches to invasive alien species (IAS) management Develop participatory approaches to restoration and link restoration to revitalizing indigenous and local knowledge Raise level of financial support for conservation Mainstream biodiversity into other sectors
Non-Governmental Organizations	Engage in transformative landscape governance networks	Encourage dietary transitions and food waste reduction Engage in expansion and enhancement of sustainable intensification Engage in ecological intensification and sustainable use of multi-functional landscapes Improve certification standards	Engage in improvement of REDD+ and PES Engage in promoting and improving certification Engage in addressing illegal logging	Engage in expansion and improved management, functionality and connectivity of (transboundary) protected areas Support management by IPLCs and Other Effective area-based Conservation Measures Engage in addressing illegal wildlife trade

6.7, 6.8}

Marine	Water	Cities	Energy	Sustainable economies
Implement global marine environmental agreements for shipping Promote comprehensive protection of biodiversity and ecosystem services of the High Seas Mobilize conservation funding	Address fragmentation of freshwater treaties Promote integrated water resource management and transboundary water management Strengthen rights- based approaches & freshwater standards	Promote sustainable urban planning Promote nature-based solutions and green infrastructure Promote increasing access to urban services	Develop standards for sustainable renewable energy projects Promote biodiversity inclusive environmental impact assessments	Promote sustainable production and consumption; circular economy models Reform trade system and World Trade Organization Promote reform of subsidies Promote reform of models of economic growth
Mainstream biodiversity conservation and promote ecosystem services Support shared and integrated ocean governance Promote stronger implementation of fisheries conservation measures Strengthen integrated management of coastal waters	Promote interlinkage among water-energy-food systems Develop integrated rights-based and participatory approach to water management Encourage stakeholder engagement Develop water-efficient agricultural practices Promote and facilitate nature-based solutions Restrict groundwater abstraction	Implement sustainable urban planning, including bioregional planning, biodiversity-friendly urban development, increasing green spaces, and creating space for urban agriculture Implement nature-based solutions and green infrastructure Reduce the impacts of cities by encouraging articulated density; discouraging car use and promoting public transportation; developing energy efficient building codes; and encouraging alternative business models Enhance access to urban services, including through sustainable urban water management, integrated sustainable solid waste management, incentive programs and participatory planning	Develop sustainable bioenergy strategies Strengthen and enforce biodiversity inclusive environmental impact assessment laws and guidelines Strengthen biodiversity compensation policies for development and infrastructure loss	Address over and under consumption through taxes on consumption, product labeling, discouraging overbuying, promotion of sharing economy Sustainable public procurement Reduce unsustainable production through taxes on resource consumption and degradation; promotion of circular economy models; capping of resource consumption; applying life cycle assessment Reform derivative and futures markets Reform subsidies by assessing impacts of all subsidies policies and long-term removal of all environmentally-unsound subsidies Application of alternative measures of economic welfare and Natural Capital Accounting; move towards steady state economics paradigm and degrowth agenda
Develop conservation programs to raise awareness on local ecosystems, species values and knowledge Engage stakeholders Contribute to global assessments and participate in the global standard setting Engage in developing and monitoring fishery certification schemes	Organize awareness raising activities Engage in nature-based solutions Engage in developing and monitoring water quality and abstraction related standards	Engage in sustainable urban planning Promote the reduction of the impacts of cities Engage in enhancing access to urban services	Participate in community led initiatives Engage in developing and monitoring bioenergy standards and schemes	Develop initiatives to discourage overbuying; engage in development of product labeling Promote circular economy Promote initiatives for transformation to sustainable economy

Decision maker	Instruments that can be included in smart policy mixes within or across issues {Tables 6.3, 6.4, 6.5, 6.6,				
	Landscape approaches	Food	Forest	Conservation	
Citizens, community groups, farmers	Engage in transformative landscape governance networks	Change to sustainable consumption (diet, reducing waste) Engage in localized food systems Engage in expansion and enhancement of sustainable intensification; ecological intensification and sustainable use of multi-functional landscapes Engage in conservation of genetic resources for agriculture	Engage in community-based forest management and co-management Change to sustainable consumption	Engage in conservation efforts	
Indigenous People and Local Communities	Engage in transformative landscape governance networks	Engage in conservation of genetic resources for agriculture	Engage in community-based forest management and co-management Engage in forest monitoring	Engage in management Engage in addressing illegal wildlife trade; sustainable wildlife management Engage in restoration and revitalization of indigenous and local knowledge	
Donor agencies	Support transformative landscape governance networks	Support reduction of food waste; localized food systems; sustainable intensification; ecological intensification	Support community-based forest management and co-management; improvement of REDD+ and PES policies; improvement and implementation certification; initiatives addressing illegal logging; enhanced forest monitoring	Support expansion and improved management, functionality and connectivity of (transboundary) PAs; management by IPLCs and Other Effective area-based Conservation Measures; addressing illegal wildlife trade Raise level of financial support for conservation	
Science and educational organizations	Engage in transformative landscape governance networks	Engage in expansion and enhancement of sustainable intensification and ecological intensification Engage in transformation food storage and delivery systems Facilitate conservation and sustainable use of genetic resources for agriculture	Support reduced impact logging Support improvement of certification Engage in enhancing forest monitoring	Analyze social and economic impacts of restoration Analyze conservation impacts of Official Development Assistance	
Corporate actors	Engage in transformative landscape governance networks	Contribute to expansion and enhancement of sustainable intensification Contribute to ecological intensification Transform food storage and delivery systems Improve certification standards Engage in conservation of genetic resources for agriculture	Implement reduced impact logging Engage in improvement and expansion of forest certification Address illegal logging and trade in illegal timber	Engage in addressing illegal wildlife trade Engage in restoration Raise level of financial support for conservation	

6.7, 6.8}

Marine	Water	Cities	Energy	Sustainable economies
Engage in policy decision making, remedial actions, and educational programs Engage in awareness campaigns to influence consumer behaviour and consumption	Participate in ecosystem restoration activities Engage in collaborative initiatives	Engage in sustainable urban planning Engage in development and maintenance of nature-based solutions and green infrastructure Change to sustainable consumption (reduced waste, increased public transport) Engage in initiatives to access to urban services	Actively engage in community led activities	Engage in reduced consumption movements and change towards sustainable consumption; local reuse or fix-up initiatives Support companies with sustainable production models
Engage in coastal management and MPA Collaborate in integrated management of marine resources	Support co-management regime for collaborative water management Engage, where appropriate, with payment for ecosystem services or other local water ecosystem services provisioning schemes	Engage in advocacy networks for sustainable cities	Participate in formulating sustainable bioenergy strategies Engage in the implementation of Free, Prior and Informed Consent	Engage in discussions over values in a sustainable economy and good life
Support funding sources in the High Sea that ensure conservation Ensure funding promotes sustainable fishing practices Promote innovative and longer term financing through market based mechanisms	Establish standards and guidelines that improve water quality and integrate social and environmental considerations	Support sustainable urban planning Support initiatives to enhance access to urban services	Promote innovative financing for sustainable infrastructure Establish sustainable bioenergy guidelines	Support initiatives to transform to sustainable economy Fund projects on use of alternative welfare measures
Promote mainstreaming climate change adaptation and mitigation into marine and coastal governance regimes	Promote awareness raising activities	Support sustainable urban planning, development of nature-based solutions and green infrastructure, reduction of the impact of cities and enhancing access to urban services	Promote awareness raising activities	Support circular economy; further include BES in life cycle assessment Research on environmental impacts of futures and derivatives Support reform of models of economic growth
Engage in CSR activities, certification and best practices in fisheries and aquaculture production methods Mobilize conservation funding for the oceans Take account of ecological functionality into coastal infrastructure	Engage in setting water quality and abstraction related standards Engage in water restoration schemes Promote sustainable investment in water projects Invest in clean and environmentally sound technology	Engage in sustainable urban planning Develop energy efficient buildings Engage in alternative business models Engage in partnerships and other initiatives to enhance access to urban services	Engage in setting sustainable bioenergy strategies Promote sustainable infrastructure practices Strengthen biodiversity compensation policies Promote innovative financing for sustainable infrastructure	Implement sustainable sourcing practices; design for sustainability; engage in development of product labeling; apply life cycle assessment; contribute to circular economy Engage in corporate social responsibility Engage in reform of models of economic growth

6.1 INTRODUCTION

In recent decades, the extent and scope of societal responses to environmental problems, including biodiversity decline, have been extensive and diverse. The outcomes, however, have been mixed across sectors and levels of governance, with limited success in reverting global trends and in addressing the root causes of degradation. Lessons and opportunities also abound, amid new challenges and scenarios. This chapter discusses opportunities and challenges for all decision makers to advance their efforts in meeting, synergistically, internationally agreed goals for sustainable development, biodiversity conservation, and climate change mitigation and adaptation. In doing so, the chapter builds on the analysis in the previous chapters, which have identified direct and indirect drivers of change, evaluated progress or lack of progress in achieving the Aichi Biodiversity Targets, the Sustainable Development Goals (SDGs), and several environmental conventions, and assessed plausible scenarios and possible pathways. Previous chapters of the present assessment show that, despite progress on various goals and targets and improvements in environmental indicators in many regions, species diversity, ecosystems functions and the contributions they provide to society continue to decline, further reinforcing both environmental and societal problems.

While progress can be made to achieve the Aichi Biodiversity Targets, the CBD 2050 Vision and the SDGs using current policies, practices and technologies, and within current national and international governance structures, these are not enough to address current and projected trends. It has become widely recognized that transformative change is needed to fully realize these ambitions (CBD/SBSTTA/21/5, 12 October 2017; CBD/SBSTTA/21/2, 15 September 2017). In fact, the adoption of the SDG shows that the international community has committed itself to such transformative change: "*We are determined to take the bold and transformative steps which are urgently needed to shift the world on to a sustainable and resilient path*" (UNGA, 2015).

Transformative change can be defined as a fundamental, system-wide reorganization across technological, economic and social factors, including paradigms, goals and values (IPBES, 2018a; IPCC, 2018). Such fundamental, structural change is called for, since current structures often inhibit sustainable development, and actually represent the indirect drivers of biodiversity loss (Díaz *et al.,* 2015) (See Section 6.2. below). Transformative change is thus meant to simultaneously and progressively address these indirect drivers. The character and trajectories of this transformation will be different in different contexts, with challenges and needs differing, among others, in developing and developed countries.

Transformative change is facilitated by innovative governance approaches that incorporate existing approaches such as integrative, inclusive, informed and adaptive governance. While such approaches have been extensively practiced and studied separately, it is increasingly recognized that together they can contribute to transformative change (see section 6.2). The concept of governance refers to the formal and informal (and public and private) rules, rule-making systems, and actor-networks at all levels of human society (from local to global) that are set up to steer societies towards positive outcomes and away from harmful ones (adapted from Biermann *et al.,* 2010).

In response to the interconnected challenges of sustainable development, biodiversity conservation,

Table 6 2 **List of decision makers.**

	Decision maker
1	Global and regional (inter)governmental organizations (UN, MEA secretariats etc.)
2	National, sub-national and local governments
3	Private sector
4	Civil society, including: • Citizens (households, consumers), community groups, farmers • NGOs (e.g., environmental, human development, consumer, trade unions)
5	Indigenous Peoples and Local Communities (IPLCs)
6	Donor agencies (public and private)
7	Science and educational organizations

and climate change identified in previous chapters, this chapter organizes its analysis on the options for decision makers around sustainability pathways in five domains: terrestrial landscapes (6.3.2), marine, coastal and fisheries (6.3.3); freshwater (6.3.4); cities (6.3.5); and energy and infrastructure (6.3.6). Finally, the chapter discusses approaches and conditions that enable transformation towards sustainable economies (6.4). Each of these major issues is considered in terms of short- and long-term options, and against possible obstacles for decision makers to enable transformative change. The chapter distinguishes different decision makers (see **Table 6.2**).

Our analysis of options implemented so far shows that, already in the short-term (before 2030), all decision makers can contribute to the transformation towards sustainability by applying existing policy instruments, which need to be enhanced and used together strategically in order to become transformative – in other words – not only address direct drivers, but especially indirect drivers. The existing instruments discussed in sections 6.3 and 6.4 can thus be further enhanced based on the lessons learned from earlier experiences with implementation. In the long-term (today-2050), transformative change will entail additional measures and governance approaches to change technological, economic, and social structures within and across nations.

Below, the chapter first discusses transformative change and transformative governance (section 6.2), after which the options for decision makers on the main issues are discussed (section 6.3). Section 6.4 highlights more generic options for a sustainable economy. The options in sections 6.3 and 6.4 are based on a systematic literature review of existing and emerging governance instruments and approaches. The review especially highlights lessons relevant to transformative governance, including cross-sectoral approaches and synergies and trade-offs between different societal goals, the impact of telecoupling of distant drivers, and lessons learned from incorporating diverse values, rights-based approaches and equity concerns in decision making and policy implementation (see section 6.2).

Due to the scope of the chapter's coverage and the extent of the literature review supporting it, the chapter includes a Supplementary Material document. A significant amount of the literature evidence supporting statements made in the chapter are presented there, thus we encourage the reader to consult Supplementary Material when cross-references are made in the main chapter.

6.2 TOWARDS TRANSFORMATIVE GOVERNANCE

As introduced in 6.1, transformative change can be defined as societal change in terms of technological, economic and social structures. It includes both personal and social transformation (Otsuki, 2015), and includes shifts in values and beliefs, and patterns of social behaviour (Chaffin *et al.,* 2016).

Transformative change has emerged in the policy discourse and is increasingly seen as both necessary and inevitable for biodiversity-related issues and sustainable development more broadly. The Convention on Biodiversity (CBD), European Environment Agency (EEA, 2015), OECD (OECD, 2015), World Bank (Evans & Davies, 2014), UN (UNEP, 2012), UNESCO (ISSC/UNESCO, 2013), European Union, national governments and the German Advisory Council on Global Change (WBGU, 2011), for example, have over the past years launched reports and policy programs in support of sustainability transformations or transitions. This attention is based upon the increasing understanding of the persistency of the complex sustainability challenges we face: in spite of high ambitions, policy commitments, large-scale investments in innovation and voluntary actions, our economies are still developing along unsustainable pathways pushing ecological boundaries (Rockstrom *et al.,* 2009; Future Earth, 2014). To escape this path-dependency it is increasingly clear that structural, systemic change is necessary, and continuing along current trajectories increases the likelihood of disruptions, shocks and undesired systemic change.

This process of nonlinear systemic change in complex societal systems has become the object of research especially since the late 1990s under the headers of 'transformation' (Feola, 2015; Olsson *et al.,* 2014; Folke *et al.,* 2010; Moore *et al.,* 2014) and 'transition' (Geels, 2002; Grin *et al.,* 2010; Markard *et al.,* 2012; Rotmans *et al.,* 2001; van den Bergh *et al.,* 2011; Turnheim *et al.,* 2015). While having different disciplinary origins (Hölscher *et al.,* 2018), both terms are increasingly used in a similar way referring to a particular type of change, namely nonlinear and systemic shifts from one dynamic equilibrium to another (Patterson *et al.,* 2016). A range of different scientific disciplines has studied underlying patterns and mechanisms of such transformation. Prominent fields of research include resilience, sustainability transition, innovation studies and social innovation research. While these debates have often remained rather a-political, a more critical perspective is emerging (see e.g. Blythe *et al.,* 2018; Chaffin *et al.,* 2016; Lawhon & Murphy, 2012; Meadowcroft, 2009; Scoones *et al.,* 2015) that incorporates politics, power, legitimacy and equity issues, recognizing that transformations include the making of "hard choices" by decision makers (Meadowcroft, 2009).

Governing transformative change, or *transformative governance,* can be defined as "an approach to environmental governance that has the capacity to respond to, manage, and trigger regime shifts in coupled socio-ecological systems at multiple scales" (Chaffin *et al.,* 2016). Transformative governance is deliberate (Chaffin *et al.,* 2016), and inherently political (Blythe *et al.,* 2018), since the desired direction of the transformation is negotiated and contested, and power relations will change because of the transformation (Chaffin *et al.,* 2016). Current vested interests (including in certain technologies) are thus expected to inhibit, challenge, slow down or downsize transformative change, among others through "lock-ins" (see e.g., Blythe *et al.,* 2018; Chaffin *et al.,* 2016; Meadowcroft, 2009). The debate on the related term "transition management" (Rotmans & Loorbach, 2010) points to the importance of (facilitating) emergent and co-evolutionary changes in cultures, structures and practices that challenge incumbent 'regimes' (Frantzeskaki *et al.,* 2017). This in itself requires forms of governance that complement more institutionalized, consensus-based and incremental policies by facilitating transformative actor-networks, back-casting processes, strategic experimentation and reflexive learning.

Transformative governance often needs a 'policy' or 'governance' mix aimed at navigating transformations (Kivimaa & Kern, 2016; Loorbach, 2014; Berkes *et al.,* 2008). In such a mix, instruments that facilitate the build-up of alternatives, the gradual change of institutional structures and the managed phase-out of undesirable elements need to be combined, dynamically based on a systemic understanding of the present transition dynamics (Loorbach *et al.,* 2017). How this is operationalized depends on the type of organization and level of operation and the types of (transformative) capacities, instruments and methods available (Wolfram, 2017; Fischer & Newig, 2016; Patterson *et al.,* 2016). Through co-creative multi-actor processes (Avelino & Wittmayer, 2015; Brown *et al.,* 2013) of seeking joint understandings of collective transition contexts and formulating shared desired future directions, different actors can align long-term agendas and more strategically use and implement short-term actions to guide and direct emerging transitions towards sustainable futures.

Transformative change thus needs innovative approaches to governance. Such transformative governance can incorporate different existing approaches, which we group into four domains, namely integrative, inclusive, informed and adaptive governance. While these approaches have been extensively practiced and studied separately, their combined contribution to enabling transformative change has not yet been thoroughly explored.

Transformative governance is: 1) *integrative,* since the change is related to and influenced by changes elsewhere (at other scales, locations, on other issues) (see e.g., Chaffin *et al.,* 2016; Karki, 2017; Reyers *et al.,* 2018; Wagner & Wilhelmer, 2017); 2) *informed*, based on different and credible knowledge systems (Blythe *et al.,* 2018; Chaffin *et al.,* 2016; Couvet & Prevot, 2015); 3) *adaptive,* based on learning, experimentation, reflexivity, monitoring and feedback (Colloff *et al.,* 2017; Chaffin *et al.,* 2016; Laakso *et al.,* 2017; Meadowcroft, 2009; Otsuki, 2015; Rijke *et al.,* 2013; Wagner & Wilhelmer, 2017); and finally 4) *inclusive* since transformative change per definition includes different types of actors, interests and values, and needs to address issues of social justice (Chaffin *et al.,* 2016; Otsuki, 2015; Blythe *et al.,* 2018; Li & Kampmann, 2017; Meadowcroft, 2009; Thomalla *et al.,* 2018; Wolfram, 2016). Below we elaborate on each of these four approaches to governance (not presented in order of importance).

6.2.1 Integrative governance: ensuring policy coherence and effectiveness

Since the middle of the 20th century, hundreds of multilateral environmental agreements, governmental policies and (public-) private initiatives have been developed, many of which are focused on, or relevant for, biodiversity. Moreover, different economic and policy sectors (including biodiversity conservation, climate change, agriculture, and mining) are often governed in silos at all levels of governance. This raises questions per level of governance and across levels of governance on *synergies and trade-offs* between different societal goals (see e.g., Mauerhofer & Essl, 2018). This is especially important for transformative change – the SDG cannot all be achieved simultaneously if they are not approached in an integrative manner – as recognized by the UN, which have stated that the goals and their targets are "integrated in indivisible" (UNGA, 2015).

This fragmentation and complexity of the governance for sustainable development are well recognized among scholars (see e.g., Alter & Meunier, 2009; Bogdanor, 2005; Rayner *et al.,* 2010; Tamanaha, 2008; Young, 1996), and policy makers are actively trying to enhance synergies and address trade-offs. The CBD, for example, promotes mainstreaming of biodiversity concerns into sectors impacting biodiversity, such as agriculture, forestry, fisheries, and tourism (UNEP/CBD/COP/13/24).

Integrative governance defined and the theories and practices focused on the relationships between governance instruments or systems (Visseren-Hamakers, 2015; 2018), addresses these challenges of incoherence in sustainability governance. The literature suggests various options for integrative governance, including:

- Integrated management (Born & Sonzogni, 1995), landscape governance and approaches (Buizer *et al.*, 2015; Görg, 2007; Sayer *et al.*, 2013), the nexus approach (Benson *et al.*, 2015; Rasul & Sharma, 2016), multilevel governance (Hooghe & Marks, 2003; Marks *et al.*, 1996), and telecoupling (Liu *et al.*, 2013), which bring together (or highlight the relationships between) different sectors, policies or levels of governance in trying to enhance coherence;

- (Environmental) policy integration (Jordan & Lenschow, 2010; Persson & Runhaar, 2018) and mainstreaming (Karlsson-Vinkhuyzen *et al.*, 2017; Kok and de Coninck, 2007), which aim to strengthen attention for environmental issues in other sectors;

- Interaction management (Oberthür, 2016), metagovernance, and orchestration (Abbott & Snidal, 2010; Kooiman & Jentoft, 2009), which aim to improve the relationships between (groups of) governance instruments; and

- Smart regulation and policy mixes (Gunningham and Grabosky, 1998; Mees *et al.*, 2014), which combine different instruments to be more effective together.

Additional concepts used to discuss and study integrative governance include interorganizational relations (see e.g., Schmidt & Kochan, 1977), legal pluralism (Griffiths 1986; Merry, 1988), polycentric governance (Ostrom, 2010), regime complexity and fragmentation (Biermann *et al.,* 2009; Fischer-Lescano & Teubner, 2003), coordination (Peters, 1998), coherence (Jones, 2002), institutional interplay or interaction (Oberthür and Gehring, 2006), governance architectures and systems (Biermann *et al.,* 2009), regime complexes (Abbott, 2012; Raustiala & Victor, 2004), and governance of complex systems (Young, 2017) (see Visseren-Hamakers, 2015, 2018). See **Box 6.1** for an example of Integrative Governance.

6.2.2 Informed governance: based on legitimate and credible knowledge

Traditionally, biodiversity governance has relied on natural science tools including red lists, monitoring and indicator frameworks, and models and scenarios to characterize, assess and project ecological values such as productivity, species diversity, or threatenedness. In addition, multidisciplinary tools containing knowledge and information about ecosystems, social systems, and economics, such as cost-benefit analysis, sustainability indicators, or integrated assessments are widely used and considered valuable for their ability to offer an integrated perspective (Ness *et al.,* 2007). Increasingly, these information tools and systems focus on the measurement, modeling and assessment of natural capital and ecosystem services (Turnhout *et al.,* 2013; McElwee, 2017).

These information tools and systems have several challenges and limitations. These include technical challenges such as standardization, data quality and availability, and interoperability and commensurability of data (Bohringer & Jochem, 2007; Kumar Singh *et al.,* 2009). More important is that they are mostly not fit for purpose to inform transformative governance. One reason is that they often focus exclusively on environmental dimensions and are insufficiently inclusive of diverse values (Turnhout *et al.,* 2013; 2018; Gupta *et al.,* 2012; Elgert, 2010). For example, biodiversity and ecosystem services models and assessments often use causal and mechanistic frameworks, such as the DPSIR (Drivers, Pressures, States, Impacts, Responses) approach, which are limited in their ability to account for both complex

Box 6 1 **Example of Integrative Governance – CCAMLR.**

The Commission on the Conservation of Antarctic Marine Living Resources (CCAMLR) manages the currently active fisheries in the Antarctic Treaty System area (Patagonian toothfish (Dissostichus eleginoides), Antarctic toothfish (Dissostichus mawsoni), mackerel icefish (Champsocephalus gunnari) and Antarctic krill (Euphausia superba)). The commission exemplifies integrative governance since it uses a precautionary ecosystem-based approach that considers not just the commercial fish species but also the wider ecosystem, and because its management objectives balance conservation goals with the rational use of living resources, while safeguarding ecological relationships. It does so by using clear decision rules to agree on catch limits in each fishery. It also relies on detailed data from the fisheries and fishery surveys, and the CCAMLR Scheme of International Scientific Observation (https://www.ccamlr.org/en/science/ccamlr-scheme-international-scientific-observation) to monitor CCAMLR fisheries and to forecast fishery closures. Members implement compliance systems that include vessel licensing, satellite monitoring of vessel movements and transshipments, together with measures to specifically address the threat of illegal, unregulated and unreported (IUU) fishing. The CCAMLR conservation measures are generally seen to be efficiently implemented and represent a leading example of an agreement between over 50 States that has been effective in conserving the living resources of a significant part of the world's ocean.

causal pathways and societal factors such as institutions and values affecting them (Svarstadt *et al.,* 2008; Breslow, 2015). Equally, the usefulness of indicator and monitoring systems is hindered by their technical and specialized nature and by the way in which they prioritize specific values over others (Turnhout, 2009; Merry, 2011).

Transformative governance calls for expanding existing information systems and tools to include indicators and parameters to assess the integrative, informed, adaptive and inclusive nature of governance processes, policies and interventions as well as their intended and unintended effects on Nature, NCP and GQL. An interesting initiative in this respect is Conservation Evidence, which aims to improve conservation practice by collating, reviewing, assessing and summarizing all available evidence on the effectiveness of conservation interventions (Sutherland *et al.,* 2004, 2014, 2017). It is conceived to be a free, open-access and authoritative resource designed to support informed decisions about how to maintain and restore global biodiversity, thereby combatting the phenomenon of evidence complacency, where evidence is not used in conservation decision-making (Dicks *et al.,* 2014; Cook *et al.,* 2017; Sutherland & Wordley, 2017).

Informing transformative governance also requires reconsideration of the relationship between knowledge and decision-making. Scientific expertise is not in all cases required for effective and legitimate action, and the relationship between knowledge and decision-making is not straightforward or self-evident (Dessai *et al.,* 2009; Kolinjivadi *et al.,* 2017; Wesselink *et al.,* 2013. Dilling and Lemos, 2011, Sutherland *et al.,* 2004; Matzek *et al.,* 2014; Pullin *et al.,* 2014). This means that existing information systems and tools will need to be adapted to produce knowledge that is inclusive of multiple values and forms of scientific and non-scientific knowledge, including indigenous and local knowledge (ILK), and that is credible, legitimate and salient for all relevant stake- and knowledge-holders (Cash *et al.,* 2003; Robertson & Hull, 2001; Mauser *et al.,* 2013; Sterling *et al.,* 2017).

A crucial element in the production of legitimate and credible information is the facilitation of dialogue and learning (Lemos & Moorehouse, 2005; Breslow, 2015; Kok *et al.,* 2017; Peterson *et al.,* 2003; Turnhout *et al.,* 2007; Voinov & Bousquet, 2010). Literature on transdisciplinarity and coproduction offers a variety of tools and methods that can be used by governments, NGOs but also in bottom-up processes, to organize processes of participatory knowledge production that are able to bridge practical, scientific and technical knowledge, as well as ILK (Tengö *et al.,* 2014, 2017; Clark *et al.,* 2016). Experiences with participatory modeling and scenario planning have shown amongst others that participants were better able to grapple with complexity and uncertainty and that scenarios developed on the basis of input from stakeholders were helpful in identifying different interests and facilitated communication between stakeholders and governments (De Bruin *et al.,* 2017; Tress & Tress, 2003; Whyte *et al.,* 2014). Similarly, participatory – or citizen science – approaches involving stakeholders in the selection and monitoring of indicators cannot just contribute to the availability of relevant data, but also to engagement with nature and enhanced decision-making (Fraser *et al.,* 2006; Danielsen *et al.,* 2014). An interesting example has come from the availability of real-time satellite data, which are used by initiatives like Global Forest Watch to support national and sub-national governments, civil society and the private sector to engage in forest monitoring and conservation (FAO, 2015; GFW, 2017; Nepstad *et al.,* 2014; Assunção *et al.,* 2015).

However, the application of these inclusive and participatory approaches so far is limited (Brandt *et al.,* 2013), and their ability to produce positive outcomes for problem solving and stakeholder empowerment depends on the presence of an enabling institutional context (Armitage *et al.,* 2011) which is able to effectively address unequal power relations between stake- and knowledge-holders (Nadasdy, 2003; Dilling & Lemos, 2011).

6.2.3 Adaptive governance: to enable learning

Transformative change is in essence adaptive – it represents a learning process that needs regular opportunities for reflection on to what extent and how progress is being made, the main bottlenecks, and the best ways forward. Adaptive governance is a result of continuously learning about and adjusting responses to uncertainty, social conflicts and complexity in socio-ecological systems (Chaffin *et al.,* 2014; Dietz *et al.,* 2003; Walker *et al.,* 2004; Folke *et al.,* 2005; Folke, 2006; Karpouzoglou *et al.,* 2016).

Adaptive governance includes policy processes that highlight uncertainties, developing and evaluating different hypotheses around a set of outcomes and structuring actions to evaluate these ideas (Berkes *et al.,* 2003; Paul-Wost, 2009). Adaptive governance also focuses on enhancing the resilience of socio-ecological systems by increasing their capacity to adapt, and by recognizing the importance of learning in coping with change and uncertainty (Evans, 2012). Studies on adaptive governance advocate for an experimental approach to governing such as creating institutions that can experiment with different solutions and make adjustments in the process (Holling, 2004).

There are various challenges stated in the literature that can be seen as problematic in engaging with an adaptive governance paradigm. According to Gunderson (1999) these are inflexible social systems, ecological systems that lack resilience, and technological incapacity to design experimental and innovative approaches. Also, the question of scale is essential in adaptive governance mechanisms. The scale for adaptive governance responses needs to be adapted to the social and ecological nature of the problem with sufficient response flexibility within and between political boundaries (Cosens, 2010, 2013; Huitema *et al.,* 2009; Termeer *et al.,* 2010).

Adaptive management, through monitoring and feedback, is widely recognized as a management approach to ensure effective conservation (Walters, 1986). Several studies confirm the benefits of adaptive management and “learning through doing” (Kenward *et al.,* 2011; CBD, 2004; Bern Convention, 2007), and adaptive management has been applied in the ecosystem approach in order to deal with the complex and dynamic nature of ecosystems and the absence of complete knowledge or understanding of their functioning (CBD, 2017). According to Lebel *et al.* (2006), adaptability is determined by two factors: (1) the absolute and relative forms of social, human, natural, manufactured, and financial capital, and (2) the system of institutions and governance. In order to enable a capacity to adapt, it is crucial to build trust and shared understanding between diverse stakeholders to motivate co-learning and adaptation. Accordingly, deliberation and polycentric governance are offered as tools for enabling adaptive governance.

Dietz *et al.* (2003) propose a general list of criteria necessary for adaptive governance: inclusive dialogue between resource users (analytic deliberation); complex, redundant, layered institutions (nesting); mixed institutional types (e.g., market- and state-based); and institutional designs that facilitate experimentation, learning, and preparation for change. See **Box 6.2** for an example of adaptive governance.

6.2.4 Inclusive governance: ensuring equity and participation

Inclusive governance refers to governance approaches through stakeholder engagement, including Indigenous Peoples and Local Communities, in decision-making processes. It is argued that inclusive governance improves the quality of decisions and secures legitimacy for the decisions that are taken. Reform of decision-making processes is also necessary to enhance accountability and legitimacy (Keohane, 2003; Bernstein, 2005; Biermann & Gupta, 2011; Evans, 2012).

Participatory mechanisms that introduce dialogue and negotiation can be used to discover varying and potentially competing values and knowledge systems and identify options for more equitable decisions and implementation of these decisions, and enable learning (see e.g. Innes and Booher, 1999). However, power asymmetries can also affect the manners in which values and knowledge systems are represented in such participatory platforms. Policymaking processes have often inadequately addressed minority groups or the interests and values of people who are actually or potentially affected, directly or indirectly. Procedural equity deals with power asymmetries that affect whose voice is heard and who has a say in access and control of nature (McDermott *et al.,* 2013).

Deliberative processes are widely recognized by practitioners as useful in many contexts, including urban planning, healthcare and water governance (Andersson & Ostrom, 2008; Neef, 2009; Parkins & Mitchell, 2005). Deliberative approaches are based on the assumption that competing interests and values can only be discovered, constructed and reflected in a dialogue with others (Rhodes, 1997; Dryzek, 2000; Kenter, 2016). Examples of deliberative institutions are citizen juries, consensus conferences and focus groups (Pelletier *et al.,* 1999; Smith, 2003; Lienhoop, 2015). Deliberative approaches are mostly applied at the local level but can also be used at other levels of governance Deliberative valuation can also capture the interests of future generations (Soma & Vatn, 2010; Stagl, 2006; Sagoff, 1998).

Deliberation is considered to be an integrating and bridging approach to valuation (Pascual *et al.,* 2017). Howarth and Wilson (2006) also describe the ways in which deliberative monetary valuation could contribute to social fairness. However, after deliberation it will nevertheless be essential that results be articulated in a metric that is comparable with conventional ecosystem service valuation techniques such as the contingent valuation method (Wilson & Howarth, 2002).

Box 6 2 **Example of Adaptive Governance – Urban green spaces and urban agriculture:**

Uses of vacant lots in urban areas are increasingly recognized as important sites for enhancing provisioning of nature’s contributions, such as water provisioning or climate regulation, and can also be used for food provisioning through urban agriculture. Adaptive governance principles have been realized in several “land bank” systems in the USA, such as in Cleveland, which join public and private organizations to purchase or reclaim parcels and then manage them adaptively for multiple objectives. Such strategies include plans to increase connectivity between lots and incorporate community involvement in lot management (Green *et al.,* 2016).

Inclusive governance to enhance transformative change thus needs to consider the importance of including diverse value systems, rights-holders, genders and IPLCs. These are discussed in more detail below (see **Box. 6.3** for an example of inclusive governance).

6.2.4.1 Value Systems

Decisions – made at the individual or institutional level and at different scales – are necessarily embedded in a given value system, historically rooted in the socio-cultural context and power relations; yet, such value systems may not be explicitly reflected upon (Barton *et al.,* 2018; Berbés-Blázquez *et al.,* 2016). Depending on whether a unidimensional or a more diverse (value pluralism) lens is applied by the decision maker, policy objectives, as well as policy instruments will be determined differently through formal and informal institutions (Pascual *et al.,* 2017; also see Chapter 1). Legal, economic and socio-cultural instruments currently regulating the use of nature and its contributions usually fail to address plural and multiple values of nature, instead they focus on unidimensional values (Chan *et al.,* 2016; Kolinjivadi *et al.,* 2017; Tallis *et al.,* 2014; Spangenberg & Settele, 2016) (See Supplementary Materials 6.1.1 for a discussion on market-based instruments). Additionally, they often have unintended consequences, such as motivational crowding[1] (Rode *et al.,* 2015; Vatn, 2010; Vatn *et al.,* 2014), trade-offs and conflicts (Kovács *et al.,* 2015; Turkelboom *et al.,* 2018, Whittaker *et al.,* 2018), or impacts on justice and power relations (Berbés-Blázquez *et al.,* 2016; Pascual & Howe, 2018; Sikor, 2014). Being transparent about underlying value systems and accommodating plural values and knowledge forms in decision-making widens collaboration and creates more inclusive institutional arrangements (Ainscough *et al.,* 2018; O'Neill & Spash, 2000). However, decision making in this context might be technically challenging (Dendoncker *et al.,* 2018; Phelps *et al.,* 2017; Primmer *et al.,* 2018), because value articulation needs to be equitable; conflicts often emerge between stakeholders holding different values; and plural and incommensurable values are difficult to operationalize in decision making (e.g., include in accounting), among others.

6.2.4.2 Rights-based approaches

Rights-based approaches, at the substantive and procedural level, are multifaceted, and crucial to various aspects of governance including inclusive (e.g., participation rights) and informed (e.g., information rights) governance. In order to promote GQL, national laws and policies integrate the substantive right to a healthy environment, life, water, food, standard of living, and health (Knox, 2013, 2017; Draft Framework Principles on Human Rights and the Environment, 2018). Regional and national laws and policies also integrate procedural rights to information and participation in decision-making (Aarhus Convention, 1998; *Escazú Agreement, 2018;* Knox, 2013, 2017).

In addition, strong *land and sea rights*, including ownership and use rights, can promote local empowerment, reduce tensions between the authorities and resource users, and can be successfully integrated in community management of forests, use of non-timber forest products, communal grazing lands and subsistence fisheries (Oxfam *et al.,* 2016; FAO, 2012; Ring *et al.,* 2018; Acosta *et al.,* 2018; Stringer *et al.,* 2018). Granting land and sea rights to IPLCs is also a critical means for connecting IPLCs with environmental protection policies, including economic instruments such as carbon offsets, REDD+, PES and micro-credits (Gray *et al.,* 2008; de Koning *et al.,* 2011; van Dam, 2011; McElwee, 2012; Larson *et al.,* 2013; Duchelle *et al.,* 2014; Sunderlin *et al.,* 2014). As for *customary rights*, examples confirm that if competing interests between state and customary systems are adequately balanced, policy measures incorporating customary rights are likely to protect traditional values and ILK, respect local power structures and institutions of IPLCs, and contribute to biodiversity conservation (Acosta *et al.,* 2018; Willemen *et al.,* 2018). *Animal rights* are an example of non-anthropocentric development that recognizes intrinsic values of animals and the (ecological) interdependence of humans and animals (Birnie *et al.,* 2009; Kymlicka & Donaldson, 2011). *Rights of Nature* refers to the entitlement of nature with rights as a collective subject of interest, acknowledging its intrinsic values (Rühs & Jones, 2016; Gordon, 2017; Kotzé & Calzadilla, 2017; Rogers & Maloney, 2017). Policy options for the recognition of such rights often imply the articulation of a co-management regime (e.g., Whanganui River, New Zealand; Strack, 2017), and have been codified in national constitutions (e.g., Ecuador; Kauffman & Martin, 2017), national legislation (e.g., Bolivian Law of Mother Earth; Pacheco, 2014) and in local policies (e.g., United States; Sheehan, 2015). Also see Supplementary Materials section 6.1.2.

6.2.4.3 Gender

Gender literacy, women's empowerment, financial support, gender responsive approaches and integrating gender into nature conservation solutions are crucial to reinforce links between gender and biodiversity, achieve biodiversity objectives, and SDG 5 (gender equality) (CBD SBI/2/2 Add.3 (2018); IUCN, 2017). Lack of gender sensitive funding mechanisms and structural inequality hinder gender mainstreaming at the national and local level (Sweetman, 2015; UNEP, 2016). While *gender rights* acknowledge the interdependence between gender, biodiversity conservation

1. Motivational crowding means that the intended motivational impact of an incentive interacts and often changes the internal / intrinsic motivations of actors. Crowding-in means that an external incentive strenghtens intrinsic motivations, while crowding-out means that the incentive decreases intrinsic motivations to protect biodiversity (Rode *et al.,* 2015; Vatn *et al.*, 2014).

and sustainable use of resources (CBD Gender Plan of Action, 2008; Aichi Target 14, 17 and 20), poverty, religious and cultural practices (e.g., when gender disparities are entrenched in cultural and religious beliefs), and unequal social, economic and institutional structures are some of the key obstacles women encounter (CBD/IUCN, 2008; FAO, 2013; UNEP, 2016). The fundamental role women play in, among others, agriculture, forestry, fisheries, tourism, water management, wildlife management, and nature conservation and management underpin the need for effective participation in decision-making (Jenkins, 2017; Howard, 2015). To mainstream gender considerations, governments can take actions in policy (e.g., mainstream gender into NBSAPs), organizational (e.g., giving women collective and individual voice, gender equality training and awareness-raising among decision makers, and gender responsive budgets), delivery (e.g., participatory mechanisms, capacity development and empowerment to enable effective participation), and constituency (e.g., ensure consistency with relevant conventions) spheres (CBD Decision XII/7 (2014).

6.2.4.4 IPLCs and ILK

Inclusive governance requires robust participatory mechanisms supporting the inclusion of IPLCs in policies and planning decision affecting them and the environment at large (Bray *et al.,* 2008, 2012; Ojha *et al.,* 2009; Kerekes & Williamson, 2010; Kothari *et al.,* 2012, 2013; Mooney & Tan, 2012; Buntaine *et al.,* 2015). As discussed in chapter 2, IPLCs hold territorial rights and/or manage a substantial proportion of the world's conserved nature, freshwater systems, and coastal zones, providing contributions to society at large (Maffi, 2005; Gorenflo *et al.,* 2012; Renwick *et al.,* 2017; Garnett *et al.,* 2018). There is well-established evidence that IPLCs can develop complex, sophisticated, innovative and robust institutional arrangements and management systems for successfully governing the management of watersheds, coastal fisheries, forests and grasslands and a variety of biodiversity-rich landscapes around the world (Ostrom, 1990; Berkes, 1999; Agrawal, 2001; Colding & Folke, 2001; Lu, 2001; Toledo, 2001; Gadgil *et al.,* 2003; Bodin & Crona, 2008; Pacheco, 2008; Waylen *et al.,* 2010; Basurto *et al.,* 2013; Stevens *et al.,* 2014; Fernández-Llamazares *et al.,* 2016) to govern their land- and seascapes in ways that align with biodiversity conservation (ICC, 2008, 2010; Stevens *et al.,* 2014; Ens *et al.,* 2015, 2016; Trauernicht *et al.,* 2015; Blackman *et al.,* 2017; Schleicher *et al.,* 2017; Vierros, 2017).

The inclusion of IPLCs in governance can be enhanced through processes of knowledge coproduction at local, national and global scales (Brondizio & Le Tourneau, 2015; Sterling *et al.,* 2017; Wehi & Lord, 2017, Turnhout *et al.,* 2012; Tengö *et al.,* 2014, 2017; FPP & CBD, 2016; see also 6.2.2 and Chapter 1). Such enhanced participation has been shown to improve dialogue and advance the legitimacy of decisions and the recognition of the value and rights of IPLCs (Schroeder, 2010; Redpath *et al.,* 2013; Brugnach *et al.,* 2014; Wallbott, 2014, Brodt, 1999; Young & Lipton, 2006; Berkes, 2009; Davies *et al.,* 2013; Robinson *et al.,* 2014; Stevens *et al.,* 2014; Gavin *et al.,* 2015; Alexander *et al.,* 2016; Berdej & Armitage, 2016, Ostrom, 1990; Gibson *et al.,* 2005; Hayes, 2006, 2010; Chhatre & Agrawal, 2008, 2009; Waylen *et al.,* 2010; Porter-Bolland *et al.,* 2012; Reyes-García *et al.,* 2012; Gavin *et al.,* 2015; Martin *et al.,* 2016). However, long-term capacity development, empowerment and continued funding support are critical conditions to ensure IPLCs involvement in biodiversity conservation, including specifically women, youth and non-Indigenous communities (Brooks *et al.,* 2009; Ricketts *et al.,* 2010; Eallin, 2015; Escott *et al.,* 2015; Reid *et al.,* 2016; Reo *et al.,* 2017).

There are many tools available to set up such inclusive and participatory mechanisms (Green *et al.,* 2015; Pert *et al.,* 2015; Brondizio & Le Tourneau, 2016; Schreckenberg *et al.,* 2016; Fernández-Llamazares & Cabeza, 2017; Zafra-Calvo *et al.,* 2017), including IPLC-led codes of ethical conduct in conservation (e.g., Akwe: Kon Guidelines and The Tkarihwaié:ri Code of Ethical Conduct; CBD, 2004, 2011), the Free, Prior and Informed Consent principle (Cariño, 2005; Doyle, 2015; Herrmann & Martin, 2016; MacInnes *et al.,* 2017; UNDRIP, 2007), and tools for dialogue such as the Whakatane Mechanism (Freudenthal *et al.,* 2012; Sayer *et al.,* 2017), as well as legal approaches that draw inspiration from ILK and customary institutions (Archer, 2013; Hutchinson, 2014; Akchurin, 2015; Humphreys, 2015; Strack, 2017; also see rights-based approaches above). In this vein, the laws promoting the Rights of Nature (e.g., Bolivia, Ecuador, India, New Zealand) have been, in most cases, heavily influenced by IPLC philosophies placing nature at the center of all life (Akchurin, 2015; Díaz *et al.,* 2015; Borràs, 2016; Archer, 2013; Hutchinson, 2014; Strack, 2017; Kothari & Bajpai, 2017). Moreover, securing connection to place and granting land- and sea tenure rights to IPLCs are also a critical means to ensure IPLC participation in environmental governance and key enabling factors to IPLCs' well-being (Gray *et al.,* 2008; de Koning *et al.,* 2011; van Dam, 2011; McElwee, 2012; Larson *et al.,* 2013; Sunderlin *et al.,* 2014; Sterling *et al.,* 2017). Finally, global policy arenas such as IPBES and the CBD can facilitate knowledge co-production for enhanced environmental governance (Turnhout *et al.,* 2012; Tengö *et al.,* 2014, 2017; FPP & CBD, 2016). **Figure 6.1** outlines several public policies that can facilitate IPLC inclusion in transformative governance. Also see Supplementary Materials section 6.1.3 for background material on IPLCs and ILK, and **Box 6.3** for an example of inclusive governance.

Box 6 3 Example of Inclusive Governance – The Arctic Council.

The interconnected and complex challenges faced by the Arctic have been argued to be better addressed through transformative governance, including stronger transboundary cooperation and globally-coordinated policy responses (Aksenov *et al.,* 2014; Chapin *et al.,* 2015; Sommerkorn & Nilsson, 2015; Nilsson & Koivurova, 2016; Armitage *et al.,* 2017; Edwards & Evans, 2017; van Pelt *et al.,* 2017; Burgass *et al.,* 2018). As one of the fastest changing regions on Earth (ACIA, 2004; Wassmann *et al.,* 2011; Cowtan & Way, 2014), the Arctic is facing vast social-ecological challenges that have required all levels of governance –particularly the Arctic Council– to constantly adjust their modes of operation, ensuring a governance system that is transformative, flexible across issues and sectors, and adaptable over time (Axworthy *et al.,* 2012; Young, 2012; Chapin *et al.,* 2015; Ford *et al.,* 2015). The Arctic Council (AC), established in 1996, is an intergovernmental forum promoting cooperation, coordination and interaction among the Arctic States, Arctic Indigenous communities and other Arctic inhabitants on common Arctic issues, with an overall focus on encouraging transformative change towards sustainability (Young, 2012; Bloom, 1999; Axworthy *et al.,* 2012; Nilsson & Meek, 2016). Inclusiveness is an important principle for the AC and is best reflected by the unique formal status accorded to Arctic Indigenous Peoples as Permanent Participants, sitting at the table alongside State representatives (Bloom, 1999; Young, 2005). The AC has advanced the inclusion of Indigenous knowledge and expertise in AC assessment reports by placing Indigenous representatives in the steering committees of the different constituencies, task forces and working groups of AC (Kankaanpää & Young,2012) and has catalyzed Indigenous Peoples' participation in international policymaking more generally (Koivurova & Heinamäki, 2006). The AC has however also been criticized for continuing to rely on fixed governance fundaments (e.g., soft law nature, ad-hoc funding; Koivurova, 2009) and for failing to offer the kinds of firm institutional, financial and regulatory frameworks that are considered necessary (Berkman & Young, 2006; Greenpeace, 2014; Hussey *et al.,* 2016; Edwards & Evans, 2017; Harris *et al.,* 2018). (See for more details Supplementary Materials section 6.1.4).

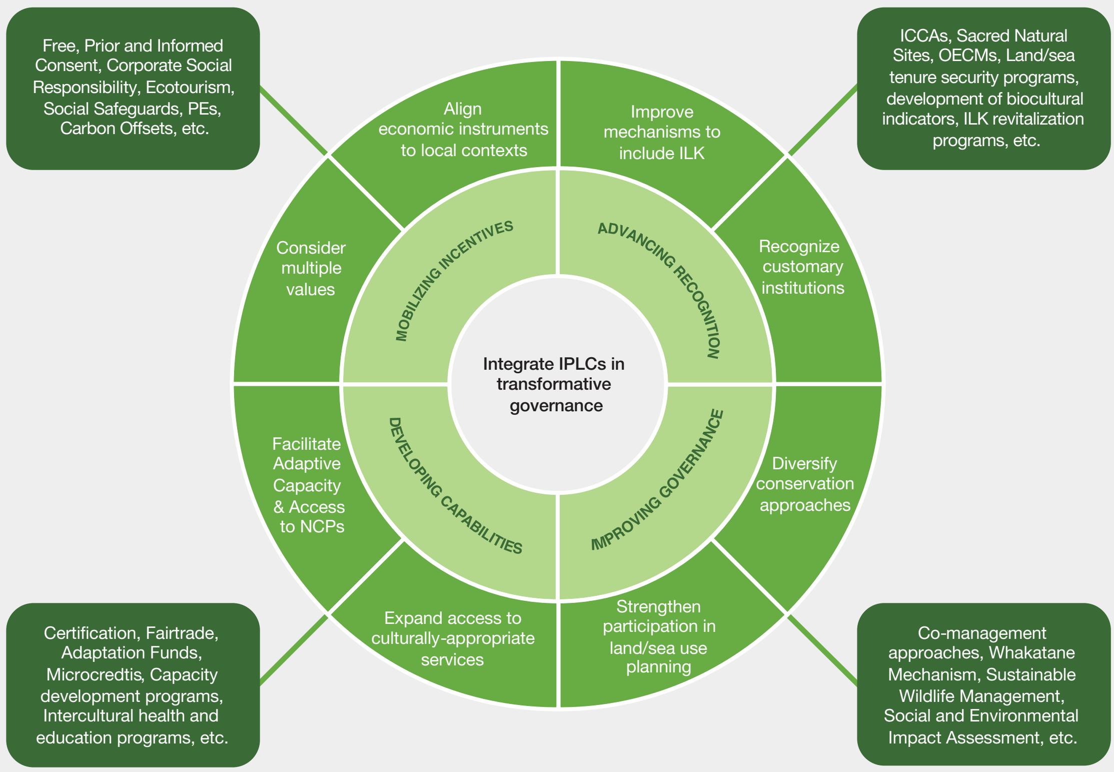

Figure 6 1 **Suite of policy opportunities and actions to better integrate Indigenous Peoples and Local Communities in transformative governance for sustainability.**

Design adapted from Strassburg *et al.* (2017).

6.3 TRANSFORMATIVE CHANGE IN AND ACROSS ISSUES, GOALS AND SECTORS

6.3.1 Introduction

As discussed in the above, the SDG are integrated and indivisible. Therefore, action on one SDG may (positively or negatively) affect progress on other SDG, and the implementation of different targets under an SDG are mutually dependent. Moreover, biodiversity is at the core of many of these complex interdependencies. To the global North and South, the comprehensive implementation of the goals offers major and different challenges to achieve sustainability in the environmental, social, and economic spheres.

Furthermore, as previous chapters have discussed, climate change is exacerbating and reinforcing other drivers of biodiversity loss and environmental degradation, such as habitat loss and degradation, agricultural expansion, unsustainable utilization, invasive alien species and pollution (particularly in marine and freshwater ecosystems; see Chapter 2.1). Various manifestations of climate change such as drought, extreme weather fluctuations, flooding, extreme heat and cold, storms, conditions for accidental fire, ocean water warming and acidification, and rising sea levels, are hindering our ability to meet the Aichi Biodiversity Targets and the SDG.

In this context, the aim of this section is to review both short-term (today-2030) and long-term (today-2050) options available to different decision makers **(Table 6.2)** to achieve the SDG on major biodiversity-related issues and policy domains, including terrestrial landscapes (6.3.2); marine, coastal and fisheries (6.3.3); freshwater (6.3.4); cities (6.3.5); and energy, mining and infrastructure (6.3.6). The overview table in each section summarizes the options that policy makers can include in policy mixes to together address the indirect drivers. The tables include the short- and long-term options, the main problems expected in their implementation, the main decision maker(s) involved, the main levels of governance involved (from the global to the local), and the main targeted indirect driver(s). Some of the common threads emerging from the synthesis below are the following:

First, integrated approaches within an SDG (various targets within one SDG) or among SDG (e.g., the water-food-energy-infrastructure nexus) offer opportunities to foster policy coherence, minimize unforeseen externalities and reduce potential conflict or tensions between different objectives or policies. Promising interventions include practicing integrated water resource management and landscape planning across scales, integrated coastal management, and bioregional scales for energy etc. In addition, policy mixes play a crucial role to address externalities and incorporate diverse values.

Second, data gathering, monitoring and reporting enable decision makers to understand the function and inter-related dynamics of nature, its contributions, and quality of life. Different types of assessment and analytical tools (e.g., cost benefit analysis, life cycle analysis, environmental impact assessment, strategic impact assessment, and participatory assessment) synthesize different types of knowledge, including indigenous and local knowledge. In addition, telecoupled information flows have the potential to contribute to monitoring, surveillance and control. Examples of these options are zero-deforestation pledges, certification schemes for key commodities or biofuel, and the use of satellite surveillance of at-sea fishing operations.

Third, collaborative efforts such as partnerships and other multi-stakeholder approaches among state, market and civil society actors can contribute towards achieving sustainability on all major issues discussed here. In addition, the development of robust, evidence-based, participatory and inclusive decision-making processes optimizes the participation of IPLCs and marginalized social groups (e.g., urban slum dwellers) in environmental governance. Enhanced participation and leadership of IPLCs in environmental processes can advance the recognition of the social, spiritual and customary values of IPLCs in environmental management decisions and influence the outcome, thereby enhancing their legitimacy.

Fourth, it is acknowledged that the effectiveness of policy instruments is context specific, and the implementation of different policy options needs to be adaptive. Moreover, the effectiveness of various policy instruments is not yet well understood and further research on the effectiveness of different policy options, separately and in combination, is necessary to achieve transformative change.

6.3.2 Integrated Approaches for Sustainable Landscapes

Landscapes are the geographical space where socio-ecological systems are shaped and develop. They are the most important source of food, water, materials and bio-energy, and provide space and quality for human habitation. Hence, landscapes are also the space where multiple land uses and values converge. Historically, landscapes have been governed by policies and decisions from different sectors and governance levels, i.e. agriculture, rural development, water, forestry, infrastructure, energy and urban planning, acting often independently without taking due consideration of the interdependencies and trade-offs among different societal objectives that often arise in landscapes.

The lack of articulation of these multiple objectives has been the cause of the large environmental, health and biodiversity loss challenges today, including the conversion and fragmentation of species habitats, one of, and in some regions the main driver of global biodiversity loss (Barnosky *et al.,* 2011; Ceballos *et al.,* 2015; Pimm *et al.,* 2014, Chapter 3 section 3.2.1), the levels of mechanization and resource inputs leading to landscape and biological homogenization (Newbold *et al.,* 2015; Pepper *et al.,* 2017), the lack of adequate attention for the protection of genetic resources of crops, trees, their wild relatives, and livestock (Collette *et al.,* 2015), the skewed representation of biodiversity in protected areas (Butchard *et al.,* 2012, 2015), and the loss of the capacity of soils, cropland and forested areas to maintain ecosystem services (Vitousek *et al.,* 1997; Schiefer *et al.,* 2016, Fornara *et al.,* 2008), including natural pest control and pollination. These challenges are associated with depletion, eutrophication and pollution of water, health problems related to undernourishment and simplified diets (United Nations, 2015), increased costs and risks in food and forestry production due to the introduction of invasive alien species (IAS), and the contribution of landscapes to greenhouse gas (GHG) emissions (FAO & ITPS, 2015, Supplementary Materials 6.2.1).

One unresolved question is how to shape landscapes that fulfil current and future needs of food and materials production, without the negative impacts on nature and society listed above. "Land-sparing" and "land-sharing" represent two extreme models about how landscapes can be shaped and refer to the degree of compatibility between different land use intensities, the conservation of biodiversity and generation of ecosystem services within a landscape (Balmford *et al.,* 2005; Fischer *et al.,* 2008; Phalan *et al.,* 2011, 2016, see also Supplementary Materials 6.2.1). This simplified dichotomy ("land sparing" vs. "land sharing") limits future possibilities (Chapter 5 section 5.3.2.1). There is increasing consensus in that visions of sustainable land-use systems will lie in between these contrasting models, by considering the specific social, economic, ecological and technological context (Fischer *et al.,* 2008; Tscharntke *et al.,* 2012; Chapter 5 section 5.3.2.1). A landscape-focused participatory approach to policy design and implementation is an option to better address dilemmas about land use allocation and intensity of use.

This section analyses the evidence on the effectiveness of policy options that could be used by different decision makers to promote the transition to sustainable landscapes. To contribute to transformative change, options for sustainable agriculture and forest management and conservation would need to be approached with policy mixes (as discussed in 6.2.1 above on integrative governance): "…a combination of policy instruments that (evolves to) influence the quantity and quality of biodiversity conservation and ecosystem service provision in public and private sectors" (Ring & Schröter-Schlaack, 2011). These mixes can include policy instruments beyond the landscape, for instance to regulate the distance drivers of change (i.e., telecouplings) (see section *Regulating commodity chains,* below), including the effect of distant consumption patterns (see section on *Encouraging dietary transitions and alternate consumption,* below).

A policy mix approach is motivated because even in simple settings, no single policy instrument is superior across all evaluation criteria (including effectiveness, cost-minimization, equity) (Vatn, 2010), and cannot possibly address all policy goals and targets. In contrast, well-integrated and implemented policy mixes can help counteract these and other deficiencies, such as economic externalities occurring with market power, unobservable behaviour and imperfect information; and address multiple jurisdictions and policy linkages across jurisdictions (Barton *et al.,* 2013). Successful policy mixes acknowledge the socio-ecological context (Andersson *et al.,* 2015), address conservation and sustainable use challenges, and recognize their cross-sectoral and multi-scale nature (Verburg *et al.,* 2013). If well planned, policy mixes can also address different objectives across the landscape, such as through a 'policy scape' perspective. A 'policy scape', understood as the spatial configuration of a policy mix (Barton *et al.,* 2013; Ezzine-de Blas *et al.,* 2016), recognizes the spatial variation of ecological and biodiversity features, suitability for sustainable food and materials production, and trade-offs between sustainable production and conservation (Schröder *et al.,* 2014; 2017).

Transformative landscape governance networks can further develop policy mixes that integrate across sectors, land uses, actors and levels of governance (Carrasco *et al.,* 2014), addressing important trade-offs among NCP in a transparent and equitable way. Options in the short and longer-term incorporate decision makers and stakeholders from within and outside the landscape while addressing power dynamics (Ishihara *et al.,* 2017; Berbés-Blázquez *et al.,* 2016). These networks are thus multi-actor (including different types of actors), multi-level (including multiple levels of governance, from the global to the local) (Verburg *et al.,* 2013), and multi-sector (including representatives from different sectors, including the entire value chain, from producer to end user) (Lim *et al.,* 2017). Decision makers and stakeholders in these networks need to recognize different values and be cognizant of power dynamics in the networks in order to enable transformative change. Any type of decision maker could initiate such networks.

The options discussed in the remainder of this section, and summarized in **Table 6.3**, can be potential elements of these policy mixes for integrated landscape approaches. They mainly include existing instruments aimed to support sustainable agriculture, sustainable forest management and biodiversity conservation, and thus represent options that can be implemented in the short term. Water governance, although an integral part of landscapes, is discussed in section 6.3.4. However, it is only when these options are strategically combined in integrated landscape approaches that transformative change towards sustainability can take place. Such approaches can be started in the short term but need to be continuously enhanced through transformative governance in the longer term.

Table 6 3 **Options for integrated approaches for sustainable landscapes.**

Short-term options (incremental and transformative)	Long-term options (in the context of transformative change)	Key obstacles, risks, spill-over, unintended consequences, trade-offs	Major decision maker(s) (see Table 6.2)	Main level(s) of governance	Main targeted indirect driver(s)
Sustainable landscapes					
Harmonized, synergetic, cross-sectoral, multi-level and spatially targeted policy mixes, developed through transformative landscape governance networks		Sectoral policy formulation; limited resources and technical capacity; limited resolution of trade-offs; lack of policies inclusive of the entire market that address leakage and telecoupling	Governments; Science and educational organizations; private sector; civil society, IPLCs	All	Economic; institution; governance
Feeding the world without consuming the planet					
Expanding and enhancing sustainable intensification in agriculture (including crops and livestock)		Limited public investment in innovation and outreach activities; limited research and innovation in production embracing sustainability principles; economic and social inequalities	FAO, OIE, governments; science and educational organizations; civil society; donors	National and sub-national	Technological; economic
Encouraging ecological intensification and sustainable use of multi-functional landscapes		Lack of cross-sectoral policy integration; potential high risk of conflict with conservation; limited spatial/territorial planning; limited capacity to resolve trade-offs; lack of understanding about production benefits from improved biodiverse/multiple-value use of land; limited landholder buy-in; pressure to further intensify ('productivist' agricultural paradigm)	Governments; science and educational organizations; private sector; civil society; donors	National; sub-national and local	Institutions; governance; economic
Improving certification schemes and organic agriculture		Limited demand for certified products; lack of landscape level coverage; risk for leakage; voluntary; tends to prioritize brokers and industries; less participation of poor farmers; requires market integration; standards unclear for consumers	Civil society; private sector; governments	Global; regional; national	Cultural; institutions; economic; governance; technological
Regulating commodity chains		Small-farmer exclusion due to high transaction costs of certification and lack of domestic markets; limited expansion of certified area; risk of limited acknowledgement of local customary rights; lack of effective external control; promotion of segregated landscapes; overlooks root causes of land-use expansion; voluntary standards	Civil society; private sector	Global; regional; national	Institutions; governance; cultural; economic
Conserving genetic resources for agriculture		Lack of integration of local genetic resources networks and global processes; lack of integration of genetic resources in biodiversity conservation; risk of increasing social and economic inequalities; lack of recognition of IPLCs and intellectual property rights; limited trait control and seed quality standards	Global and regional (inter-) governmental organizations; private sector; IPLCs; science and educational organizations	All	Institutions; governance; technological

Short-term options (incremental and transformative)	Long-term options (in the context of transformative change)	Key obstacles, risks, spill-over, unintended consequences, trade-offs	Major decision maker(s) (see Table 6.2)	Main level(s) of governance	Main targeted indirect driver(s)
Managing Large-Scale Land Acquisitions (LSLA)		Risk of leakage effects; social and economic marginalization of local farmers; increased tenure insecurity in surrounding lands	Intergovernmental organizations, private sector; farmers	All	Economic; institutions, governance
Encouraging dietary transitions		Lack of consumer awareness of environmental, health and animal welfare implications of food types; lack of effectiveness of information campaigns; voluntary labeling of products; limited market shares of certified products, labeling often emphasizing documentation not performance; low price of unsustainable food	National, subnational and local governments; private sector; citizens; NGOs, science and education organizations	All	Economic; cultural
Reducing food waste	Transformations in food storage and delivery	Failures in food distribution and storage systems; limited consumer education; wasteful marketing practices; limited recycling of food waste; wasteful supply chains and business models	Private sector; citizens (consumers); national and subnational governments; donors; science and education organizations	National; subnational; local	Institutions; governance; cultural
Improving food distribution and localizing food systems		Disconnect between production, consumption and waste management; poor integration in urban planning; limited connection between producers and consumers	National and subnational governments; private sector; citizens (consumers)	National and subnational	Economic; institutions; governance; technological
Expanding food market transparency and price stability		Opposition to government role in stabilizing food prices and food security; limited social targeting to support poor populations	Intergovernmental organizations; National governments; private sector	National	Governance; economic; institutions
Sustainably managing multi-functional forests					
Expanding and improving community-based forest management and co-management		Bureaucratic (and political) apathy; institutional resistance from forest bureaucracies	Governments; civil society; IPLCs	National; sub-national and local	Institutions; governance; demographic
Improving policies relating to PES and REDD+		Informational and other asymmetries among stakeholders; complexities in benefit sharing; unclear or contested tenure; unfavorable institutional and policy settings; over-prioritization of market incentives; limited range of ecosystem services compensated for; international disagreement; trade-offs and conflicts between carbon and other benefits (including biodiversity conservation); stakeholders not always involved in policy design	Global institutions (UN, MEAs); governments; donor agencies; civil society	All	Governance; institutions; economic; technological
Supporting Reduced Impact Logging (RIL)		Insufficient technical and financial capacity, especially in forest-rich tropical countries	Governments; science & educational organizations, private sector	National; sub-national and local	Technological; economic
Promoting and improving forest certification		Limited technical and financial capacity for forest management; low demand for certified products; lack of information among consumers	Governments; science & educational organizations; private sector; NGOs; donors	All	Economic; institutions; governance; cultural; technological
Controlling illegal logging		Weak local governance, poor level of compliance; difficulties with monitoring and traceability; insufficient reward for legal forest harvests in global timber market; difficulties with monitoring and traceability	Intergovernmental organizations; governments; private sector, donors; civil society	All	Governance; institutions; economic

Short-term options (incremental and transformative)	Long-term options (in the context of transformative change)	Key obstacles, risks, spill-over, unintended consequences, trade-offs	Major decision maker(s) (see Table 6.2)	Main level(s) of governance	Main targeted indirect driver(s)
Monitoring and regulating forest use		Insufficient technical and financial capacities; poor understanding of the needs and benefits; weak local governance; poor level of compliance; difficulties with monitoring and traceability systems	International organizations (e.g. FAO); governments; educational organizations; IPLCs	All	Governance; economic, technological
Protecting nature					
Improving management of protected areas (PAs)		Inadequate resources and weak governance; increased human pressures; climate change; limited enforcement, limited monitoring; lack of robust ecological data to assess effectiveness across spatial & temporal scales	International organizations (e.g. IUCN); governments; NGOs; donors	All	Governance; institutions; technological
	Improving spatial and functional connectivity of PAs	Isolation of PAs; geographical and ecological biases; limited spatial planning; trade-offs among societal objectives	Global organizations; governments; NGOs; donors	All	Governance; institutions; technological
	Improving transboundary PA and landscape governance	PA planning usually depends on individual governments	Global organizations; national governments; NGOs; donors	All	Governance; institutions
Recognizing management by IPLCs and OECMs		History of conflicts between IPLCs and legal PA management; potential displacement, exclusion, distress of IPLCs due to strict PA governance; unequal sharing of costs and benefits between different actors; erosion of ILK	Governments; NGOs; private sector; IPLCs; donors	All	Cultural; governance; institutions; regional conflicts
Addressing the illegal wildlife trade		Poor law enforcement; limited capacity for detection; limited surveillance; corruption; limited capacity of crime investigation	Global institutions (CITES); national governments; citizens; IPLCs; NGOs	All	Governance; cultural; economic
Improving Sustainable Wildlife Management		Lack of recognition of IPLC rights; unequal distribution of benefits; elite capture; leakage effects; lack of enforcement of law and international agreements; corruption	Governments; IPLCs; private sector; NGOs	All	Governance; institutions; economic
Manage IAS through multiple policy instruments		Legal and institutional barriers to effective management; information management challenges; lack of resources; limited perception of risks; jurisdictional issues; lack of coherent systemic and community-partnered approach to IAS management; lack of economic incentives to engage private landowners; limited engagement of IPLCs	Global organizations; governments	All	Governance; institutions; cultural; technology; economic
Expanding ecosystem restoration projects and policies					
Expanding ecosystem restoration projects and policies and link to revitalization of ILK		Uncertainty about effectiveness; limited formal and empirical evaluation of projects; risk for limited acceptance of project (neglect of community culture and values); rapid cultural change	Governments; science and education organizations; private sector; IPLCs	National and local	Technology; economic; cultural
Improving financing for conservation and sustainable development					
Improving financing for conservation and sustainable development		Lack of understanding of what financing mechanisms are most effective; priorities for financing in other sectors above biodiversity; lack of consistent monitoring of ODA for biodiversity	Global organizations; national governments; donors	Global; regional; National	Economic; governance; institutions

6.3.2.1 Feeding the world without consuming the planet

Expanding and enhancing sustainable intensification in agriculture

To address land degradation (IPBES, 2018b) and other environmental impacts of agriculture, two forms of ecological modernization are currently considered: (i) sustainable intensification (Sustainable intensification or efficiency-substitution agriculture (Duru *et al.,* 2015, Schiefer *et al.,* 2016), which aims to improve input use efficiency and minimize environmental impacts. This is currently the dominant modernization alternative (see Supplementary Materials 6.2.2; Chapter 2.3 about trends in production for marketed commodities). (ii) *biodiversity-based agriculture* aims to develop agriculture enhancing ecosystem services generated by agro-diversity (Duru *et al.,* 2015) (see section on "Encouraging sustainable use of multifunctional landscapes", below).

Efficiency-based agriculture consists of adjusting practices in specialized systems to comply with environmental regulations and follows the logic of economy of scale and expression of comparative advantages (e.g., for soil fertility, climate, knowledge, labour costs, infrastructure, and regulations) (Duru *et al.,* 2015), aiming at closing yield gaps (Mueller *et al.,* 2012, Chapter 5 section 5.3.2.1). Implementation is based on good agricultural practices (e.g. FAO), and international voluntary standards, including those on animal health and welfare of the World Organization for Animal Health (OIE), and uses also new technologies such as precision agriculture (Supplementary Materials 6.2.2).

The adoption of these practices can be supported by investment in technological development and outreach, regulations, and public and private quality standards such as voluntary certification schemes and roundtables (see sections on *Improving certification schemes* and *Regulating commodity chains*, below). One recent example of the mixes of measures that can promote this kind of agricultural modernization is the program to encourage the sustainable increase of crop yields in smallholder farms in China. In 2003–11, the country increased its cereal production by about 32% (more than double the world average), largely by improving the performance of the least-efficient farms, through a comprehensive package of measures that included public investment, development and testing of technologies adapted to specific agro-ecological zones that improved yields, conserved soils and reduced fertilizer application, and outreach and farmer engagement (Zhang *et al.,* 2013). Development of new crop varieties remains one of several areas of fundamental research that feed into this approach to increase yields and reduce the use of insecticides (Zhang *et al.,* 2013).

Efficiency agriculture is applied to both crops and livestock production. Industrial production systems produce over two-thirds of global production of poultry meat, almost two-thirds of egg production and more than half of world output of pork, with beef and milk production remaining less intensified (FAO, 2009). The environmental impacts, including water, soil and air pollution, of intensive livestock production are significant, and these systems often harbor poor animal welfare conditions (HLPE, 2016). Challenges of efficiency agriculture, including the industrial production of livestock, generally rely on high levels of anthropogenic inputs and include the extensive use of non-renewable resources such as mineral fertilizers and energy, the risk of pest resistance to agro-chemicals (Duru & Therond, 2014), human health problems associated with the use of pesticides and veterinary drugs, the homogenization of crops, and the biological deterioration of the land. This kind of intensification may trigger land conversion as has been the case of soybean expansion in South America (Fearnside, 2001; Pacheco, 2012). Shortcomings can also involve leakage effects and failure to address the conservation of semi-natural and open habitats (Supplementary Materials 6.2.2), issues due to the shift of agricultural production from small and medium household farms to international agroindustry pools (Strada and Vila 2015), and exposure to market volatility.

Encouraging ecological intensification and sustainable use of multi-functional landscapes

Land-use systems consisting of mosaics of cropland, grasslands and pastures, and forests, are widely spread globally and are critical for food security and sovereignty (Supplementary Materials 6.2.2). Encouraging use of multi-functional landscapes can be the basis for a shift towards *ecological intensification or biodiversity-based agriculture* including diversification of food sources, ecological rotation and agroforestry, promotion of agroecology with a view to promoting sustainable production and improving nutrition (McConnell, 2003). At the same time, these landscapes are the space where the largest conflicts with nature conservation can take place (Ravenelle & Nyhus, 2017), especially in the case of wildlife – human interactions.

Multi-functional landscapes also support NCP critical to IPLC diets and food systems. These are also gaining attention in the context of global discourses around food sovereignty (Patel, 2009) and cultural identity (Charlton, 2016; Coté, 2016; Kuhnlein *et al.,* 2009; Nolan & Pieroni, 2014). Many IPLCs and a wide range of rural and peri-urban populations, remain highly dependent on hunting, fishing and gathering for their diets, which play a critical role in supporting IPLC health and well-being (Kuhnlein, 2014; Kuhnlein & Receveur, 2007; ICC, 2015; Nesbitt & Moore, 2016). As such, drivers of landscape homogenization and biodiversity loss have been largely associated with rapid nutritional shifts among IPLCs, through the reduction in consumption of locally-sourced foods as well as the incorporation of industrially processed products, often leading to increasing rates of overweight, obesity and chronic disease (Popkin, 2004; ICC, 2015; Galvin *et al.,* 2015; Iannotti and Lesorogol, 2014; Reyes-García *et al.,* 2018). Measures to promote multi-functional landscapes are easier to govern when they are broadly defined and linked to values or objectives in the sector or local practices (Runhaar *et al.,* 2017). Community-driven and culturally-appropriate responses to address these changes posit a reconnection of land-based food systems and have recurrently called for supporting the recognition of IPLC food sovereignty (Wittman *et al.,* 2010; Morrison, 2011; Rudolph & McLachlan, 2013; Martens *et al.,* 2016). Also, targeting specific measures by identifying agro-ecological constraints and characteristics of farming systems such as population pressure, urbanization, governance, income and undernourishment, can further help select suitable measures to promote ecological intensification in agriculture (Sietz *et al.,* 2017) and the management of NCP based on biodiversity.

Policy options that have been implemented to promote ecological intensification of farming systems include, although not exclusively, direct payments such as agri-environmental schemes (AES) to conserve and better provision ecosystem services (Supplementary Materials 6.2.2) and to maintain and restore habitats (Montagnini *et al.,* 2004), payments for ecosystem services (PES) to protect water sources (Frickmann Young *et al.,* 2014), with biodiversity conservation as a co-benefit (see section on *Improving REDD+ and PES),* below), and standards and certification schemes (see section on *Improving Certification Schemes and Organic Agriculture*, below). A form of biodiversity-based agriculture is permanent (agri)culture, based on broad principles defined as mimicking ecological patterns, locally designed and recuperation of traditional ecological practices (Roux-Rosier *et al.,* 2018).

Technical assistance and investment (including micro-credits) have been used to promote land uses such as agro-forestry systems that enhance on-farm provisioning (e.g. timber and non-timber products in addition to crops and pastures (Montagnini, 2017, Part III) and regulating services such as carbon sequestration. Direct payments (e.g., PES) can be combined with technical assistance since they are effective in overcoming initial economic and technical obstacles to the adoption of agro-forestry practices (Cole, 2010), but the practices need short to medium-term technical support to ensure their long-term retention. These measures have been combined with REDD+ (see section on REDD+, below) to promote carbon sequestration and halt forest clearing.

Participatory approaches and compensation schemes have helped resolve conflicts between food and material production and nature conservation, including wildlife conservation in these mixed-use systems (see section on *Improving Sustainable Wildlife Management*, below) where multiple objectives converge. Finally, the farmers' level of adoption of practices in voluntary schemes (AES, PES, REDD+, technology adoption and certification schemes) is, in many instances, low and largely determines the effectiveness of the measures (Giomi *et al.,* 2018; Runhaar *et al.,* 2017). Two obstacles related to direct payments, a widely used policy instrument, include its voluntary character and that subsidies often do not cover all costs (Runhaar *et al.,* 2017). Farmers who do not voluntarily engage in nature conservation could be incentivized by showcasing farmers who have made advances, critical consumers, and stricter rules in direct payment schemes or in generic agri-environmental legislation (Giomi *et al.,* 2018). Farmers need to be motivated, able, or enabled (e.g. through investment in technological development and outreach), demanded (through regulations and quality standards as the IFOAM-Organic standard and roundtables (see *Improving Certification Schemes and Organic Agriculture*, below), and legitimized to participate and act (Runhaar *et al.,* 2017). There are also other private forms of governance including the cooperation of farmers with conservation NGOs, or compliance to conservation standards requested by companies in agricultural supply chains as part of their Corporate Social Responsibility programmes (Runhaar *et al.,* 2017).

Improving certification schemes and organic agriculture

Over the last decades, voluntary sustainability standards (VSS) and certification schemes (VCS) have become a key governance mechanism affecting land-use decisions and land-use shifts (Sikor *et al.,* 2013) aiming to mitigate the negative impacts of agricultural expansion and intensification, including deforestation (Milder *et al.,* 2014; Tscharntke *et al.,* 2015), by promoting environmental and biodiversity-friendly practices at the farm level. Studies reveal increases in the abundance or species richness of a wide range of taxa, including birds and mammals, invertebrates and arable-land flora in certified farms (Hole *et al.,* 2005; Bengtsson *et al.,* 2005; Tuomisto *et al.,* 2012; Tayleur *et al.,* 2018), and ecosystem services (Supplementary Materials 6.2.2, Kremen *et al.,* 2002; Bengtsson *et al.,* 2005; Hutton & Giller, 2003), mainly due to lower agrochemical inputs (Aude *et al.,* 2003; Hutton & Giller, 2003; Pimentel *et al.,* 2005; Birkhofer *et al.,* 2008)

However, most certification schemes are too recent to evaluate detectable impacts (Tayleur *et al.,* 2018) and results on environmental and biodiversity performance are in many cases limited (Gulbrandsen, 2010; Gulbrandsen, 2009) or variable (Bengtsson *et al.,* 2005). In some cases, certification schemes have spurred more intensive and degrading land-use practice (Guthman, 2004; Klooster,

2010) and caused higher deforestation in neighbouring old-growth forest areas (Tayleur *et al.,* 2016).

A few studies have also documented positive livelihood outcomes from certification (Bacon, 2005; Bolwig *et al.,* 2009; Gulbrandsen, 2005; Ruben and Fort, 2012) and improved management institutions, but impacts on poverty alleviation are mixed (Yu Ting *et al.,* 2016). Many schemes have exacerbated problematic political and economic inequalities (Gómez Tovar *et al.,* 2005; Ponte, 2008) or failed to enhance market access or benefits (Font *et al.,* 2007), especially for smallholder farmers (DeFries *et al.,* 2017; Tayleur *et al.,* 2018). There are also issues of high transaction costs, transparency, legitimacy and equity in certification schemes (Supplementary Materials 6.2.2; Eden, 2009; Klooster, 2010; Havice & Iles, 2015; Hatanaka *et al.,* 2005).

Certification of tropical agricultural commodities shows clear aggregations in Central America, Brazil, West Africa and parts of East Africa and Southeast Asia and has poor representation in the world's 31 poorest countries (Tayleur *et al.,* 2018), and schemes remain limited in geographic scope (Ebeling & Yasué, 2009; Rametsteiner & Simula, 2003, Tayleur *et al.,* 2016).

Certification could better contribute to sustainability goals if targeted where benefits can be optimized (Tayleur *et al.,* 2016), i.e. areas of high nature conservation value (including landscape level quality) (Hole *et al.,* 2005), in areas of social and economic development priority, and where enabling conditions exist (e.g. governmental complementary policies) (Tayleur *et al.,* 2016). Governments can facilitate the impact of certification schemes by promoting certification uptake and supporting strategic targeting. Governments involved in international aid could engage in coordinating efforts to finance certification in identified priority areas for social and economic development (Tayleur *et al.,* 2016).

Public campaigns on the environmental, health, conservation, and social benefits of certified products are likely to increase consumer demand for these products, and measures aiming to enhance social responsibility in multi-national corporations can be effective (Tayleur *et al.,* 2018). Engaging in more equitable food value chains (see sections on *Improving food distribution and localizing food systems*, *Expanding food market transparency and price stability* and *Regulating commodity chains*) have the potential to expand the geographical range and enhance social outcomes. Critical to promoting VCS that balance conservation and economic demands is: 1) managing stakeholder expectations; 2) targeting priority habitats, species and social groups and 3) implementing adequate post-certification monitoring of impacts (Yu Ting *et al.,* 2016; Tayleur *et al.,* 2018). New technology (e.g., environmental data management and sharing infrastructure, modelling, web-based communication) and data availability could help improve monitoring and assessment of certification impacts, including bio-physical (e.g., nutrient leakage, water use efficiency, biodiversity), social and economic criteria.

Regulating commodity chains

Two major efforts to regulate commodity chains, particularly for tropical agricultural products, and to deal with telecoupling issues and the unsustainable expansion of these commodities include multistakeholder fora and commodity moratorium policies. Examples of multistakeholder fora are the Roundtable on Sustainable Palm Oil (RSPO), the Roundtable on Responsible Soy (RTRS) Better Sugar Cane Initiative, and the Roundtable on Sustainable Biomaterial, which aim to engage all private stakeholders of an agricultural supply chain, including growers; processors; consumer goods manufacturers; environmental NGOs; social NGOs; banks and investors; and retailers to establish a "sustainability" standard, and unlike labels that focus on a specific market, these standards envision to transform the entire sector towards sustainability. However, the RSPO standard overlooks the root causes of palm oil expansion in the tropics, such as land rights, commodity prices, agricultural systems and market access, resulting in a rather small and local level impact of certification on biodiversity conservation (Ruysschaert & Salles, 2014; Ruysschaert, 2016). At the global level, the RSPO is promoting a segregated landscape with large-scale plantations and conservation areas. This could make sense, as large oil palm plantations are very productive. However, this fails to recognize that the main environmental and social gains can be made by supporting smallholders, who currently produce half as much as the large-scale plantations (Ruysschaert, 2016; GRAIN, 2016).

Although the RSPO standards may be based on principles of inclusive participation from each member category; consensus building; and transparency in the negotiation process (RSPO, 2013, Schouten & Glasbergen, 2011), in practice, its implementation is more complex, with RSPO certification favouring three dominant groups of stakeholders: the downstream agro-business firms, international environmental NGOs, and the largest palm oil producers (Ruysschaert, 2016). For the downstream firms, RSPO certification fulfils their initial goal to secure their business in the long-term and protect their reputation (RSPO, 2002), but it often fails to cover costs of producers, particularly, the forgone economic opportunity to convert the areas identified as high conservation value (HCV) (Ruysschaert & Salles, 2014). RSPO has tended to favour large-scale producers seeking to get access to international markets; smaller firms and smallholders are largely excluded either because they sell to domestic markets where certification is not valued by consumers, or because they find certification too costly and its managerial requirements too demanding (Ruysschaert & Salles, 2014; Ruysschaert, 2016; and Supplementary Materials 6.2.2)

The case of moratoria such as the Brazilian Soy Moratorium (Supplementary Materials 6.2.2) appears to have been more successful in delivering biodiversity conservation outcomes (i.e. halting deforestation, Rudorff *et al.,* 2011; Gibbs *et al.,* 2015) and has set the stage for other initiatives to improve the sustainability of soy production and raise the awareness of the markets, like the RTRS and the Soja Plus Program. These initiatives are additional to zero-deforestation agreements and include other issues related to environmental compliance, social justice and economic viability at the farm and the supply chain level. Although there are leakage risks due to Moratorium restrictions (Arima *et al.,* 2011), recent analysis is showing no evidence for this (Le Polain de Waroux *et al.,* 2017). In contrast, there are opportunities for soy production in degraded pasture areas without increasing deforestation; combined with the identification of suitable areas, pasture intensification techniques and controlling new deforestation, the soy supply chain in the Amazon may become a good example of reconciliation of forest conservation and agricultural production. However, despite the good results, there are still threats to the Moratorium. Policy mixes supporting this package of measures can be enhanced if they address failures related to market shares, like the lack of engagement of traders and importers and the competition with farmers not covered by the Moratorium, which may further demise the motivation of the private sector in keeping the agreement.

Conserving genetic resources for agriculture

The diversity of cultivated plants, domestic animals and their wild relatives is fundamental for food security globally (Asia, Africa, Central and South America) (McConnell, 2003; Dawson *et al.,* 2013), and essential to the adaptation of agriculture to new and uncertain patterns of climate change. Most of the global genetic diversity in agriculture is kept in low-input farming systems (McConnell, 2003), and it is central to food sovereignty and to food as a non-material contribution to GQL (Chapter 1), also in IPLCs, where it can also involve cultural keystone species which support community identity and traditional roles (e.g. taro in the Pacific, corn in Central and South America, buffalo in North America). Globally, policy options to protect genetic resources for agriculture and forestry include support to on-farm conservation (*in situ*) (Enjalbert *et al.,* 2011; Thomas *et al.,* 2012, 2015) integrated with the conservation of germplasm in gene banks (*ex situ*). *In situ* conservation requires that the farmers, livestock keepers and foresters who conserve and manage these varieties, breeds and species benefit from maintaining this global common resource (CBD, 2014 Nagoya Protocol; Collette *et al.,* 2015). The genetic diversity in agriculture underlie current debates on food and seed sovereignty, and the implications of intellectual property rights to conservation of biodiversity and plant germplasm (Coomes *et al.,* 2015, see also Chapter 2.1 section 2.1.9.1.1). The debates have involved researchers, policy makers, seed producers for the market and IPLCs, bringing tension over seed legislation, regulation and commercialization (FAO, 2004; CBD The Nagoya Protocol, 2014; European Seed Association, 2014).

The case of social networks (e.g. farmer seed networks and community seed banks (Coomes *et al.,* 2015; Pautasso *et al.,* 2013; Lewis & Mulvany, 1997), illustrate the potential and challenges of the conservation and sustainable use of local genetic resources of global significance. Seed networks are cornerstones in maintaining the diversity of crops and their wild relatives (Tapia, 2000); they account for 80-90% of the global seed transfers and supply (Coomes *et al.,* 2015) and are important channels of innovation and diversity (Coomes *et al.,* 2015), and therefore show considerable potential for innovation and transformation of agricultural systems aligned with the SDG, especially if entry points for improvement are identified (Buddenhagen *et al.,* 2017). Seed networks are found in all regions of the world: Central and South America, Africa, Asia; in the Australia, Canada, the UK and the USA, and particular types of community seed banks have emerged (Vernooy *et al.,* 2015; Dawson *et al.,* 2011; Urzedo, 2016).

Options examined in the literature include aspects of seed quality and distribution, social and economic dimensions and global governance issues. Developing quality standards for traits, seeds and other material, and quality control schemes would considerably enhance the potential for integration into global processes of sharing and exchange of genetic resources (Coomes *et al.,* 2015; Jarvis *et al.,* 2011), but the mechanisms of seed sharing require attention, so that barriers that discriminate disfavored social groups can be addressed and eliminated (Tadesse *et al.,* 2016). Vernooy *et al.* (2017) summarize a series of measures to maintain *in situ* genetic diversity, which include support to local institutions, actively protect plants and livestock breeds that can survive extreme conditions, facilitate the restoration of varieties no longer used, develop platforms to facilitate access and availability of seeds at the community level, and help access novel diversity not conserved locally. Since in many cases, farmers have few market or non-market incentives, different public measures will be necessary to protect genetic resources (Jarvis *et al.,* 2011).

Given that these resources are of global importance (see also Chapter 2.2 section 2.2.3.4.3 on agro-biodiversity hotspots and Chapter 3 on Aichi Target 13) the national and global mechanisms need to be developed and harmonized. Global mechanisms are governed by three agreements originating from different sectors: The Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization under the CBD (CBD, 2014; Nagoya Protocol), the International Treaty on Plant Genetic Resources for Food and Agriculture (ITPGRFA) (FAO, 2004), and the International Convention for the Protection of New Varieties of Plants (UPOV http://www.upov.int/portal/index.html.en). Despite efforts to harmonize implementation, there are considerable gaps in the coordination of the agreements.

Managing large-scale land acquisitions (LSLA)

Concerns about LSLA (also sometimes called "land grabbing") have increased considerably over the past decade (Borras *et al.,* 2011; Balehegn *et al.,* 2015) and include issues of food security, equity, leakage and environmental effects (Grant & Das, 2015; Coscieme *et al.,*, 2016; Borras *et al.,* 2011; Adnan, 2013). While some see land acquisitions as investments that can contribute to more efficient food production at larger scales (World Bank, 2010; Deininger & Byerlee, 2012), there are strong concerns that food security (especially at local levels) may be threatened by these large agribusiness deals (Daniel, 2011; Lavers, 2012; Golay & Biglino, 2013, Ehara *et al.,* 2018; and Supplementary Materials 6.2.2).

Displacement of smallholders from LSLA can potentially lead to impoverishment and increased (unsustainable) production elsewhere once they are removed from lands (Borras *et al.,* 2011; Adnan, 2013); these have happened with frequency in many countries in Africa, where communal land tenure authorities have allowed expropriation of locally used lands without other farmers' knowledge or compensation (Osinubi *et al.,* 2016). There is some evidence that LSLA have already led to the impoverishment of some communities and as many as 12 million people (Adnan, 2013; Davis *et al.,* 2014). In at least some cases, the causal process is that land grabs contribute to increased tenure insecurity in surrounding lands, leading farmers to shift to cultivating smaller farms with less investments, potentially leading to food shortages (Aha *et al.,* 2017). There is some evidence that land grabbing is also weakening local systems of common property management, which can make some communities less able to adapt to climate changes in the future (Gabay & Alam, 2017; Dell'Angelo *et al.,* 2017), including reducing the forest resources they may depend on as safety nets (Kenney-Lazar, 2012).

The primary policy mechanisms for combatting large scale land acquisitions have included restrictions on the size of land sales (Fairbairn, 2015); pressure on agribusiness companies to agree to voluntary guidelines and principles for responsible investment (Collins, 2014; Goetz, 2013); attempts to repeal biofuels standards (Palmer, 2014); and direct protests against the land acquisitions (Hall *et al.,* 2015; Fameree, 2016). REDD+ has the potential to provide a counterbalance with funding to combat land grabbing, but evidence is unclear if this is really happening yet or if REDD+ will mostly protect areas not under threat from large-scale investments (Ziegler *et al.,* 2012; Phelps *et al.,* 2013). Some have also accused REDD+ projects of being akin to land grabs in that they may displace smallholder agriculture without proper compensation (Lyons & Westoby, 2014; Corbera *et al.,* 2017). Future policies to regulate LSLA will need to rely on better monitoring data as a first step, as it is difficult to track the scale and impact of such LSLA.

Encouraging dietary transitions

The characteristics of today's global(ized) food system and the increasing industrialization of agricultural production, food consumption, and in particular animal protein consumption, are associated with a range of challenges, including food sovereignty, biodiversity loss, climate change, pollution, and animal health and welfare (HLPE, 2016; Steinfeld *et al.,* 2006; Garnett *et al.,* 2013; HLPE, 2016; Visseren-Hamakers, 2018; McMichael *et al.,* 2007; Jones & Kammen, 2011; Tilman & Clark, 2014). These problems are especially urgent given the fact that the global production of different animal products is expected to double by 2050 (Steinfeld *et al.,* 2006). The expansion of soybean in South America illustrates the challenges of current globalized industrial food production, with 45% of livestock feed in the EU based on soybean imported from Brazil and Argentina (EEA, 2017; Strada & Vila, 2015).

Current consumption of animal products is very unequally distributed, and animal protein can continue to play a role in ensuring food security in much of the developing world (Steinfeld & Gerber, 2010). However, substantially reducing the consumption of animal products in developed countries and emerging economies has the potential to greatly lower the negative impacts of farming while at the same time generating significant dividends in terms of people's health (Pelletier & Tyedmers, 2010; Smith *et al.,* 2013; Tilman & Clark, 2014; Bajzelj *et al.,* 2014; Ripple *et al.,* 2014; Springmann *et al.,* 2016, see also Chapter 2.3).

Different types of policy instruments aimed at lowering and changing consumption have been tried and studied (Story *et al.,* 2008; Vinnari & Tapio, 2012). Informational policy instruments aim to foster more sustainable food choices by offering information on production characteristics or health implications of food types or products. They range from certification schemes and (requiring) labels listing product ingredients or voluntary labels, signaling superior production methods (in terms of environmental, social or animal welfare aspects), to health campaigns (Reisch *et al.,* 2013), and would seem promising given a lack of consumer awareness of the implications of animal protein, an inaccuracy of messages on the health implications of (red) meat consumption, and the potential for altering relevant consumer attitudes and motivations identified by research (Boegueva *et al.,* 2017, Dagevos &Voordouw, 2013).

Economic policy instruments such as subsidies or taxes have been used to influence consumer choice via economic incentives and have shown to be particularly effective at driving dietary change, at least in developed countries (Dallongeville *et al.,* 2010; Capacci *et al.,* 2011; Mytton & Clarke, 2012; Thow *et al.,* 2014; Whitley *et al.,* 2018). Regulatory standards, in turn, prescribe what may be sold to consumers. However, the use of such policy instruments in the food sector has for the most part been restricted to the case of age-related prohibitions on the purchase of tobacco or alcohol (also see 6.4).

However, while the political *Zeitgeist* has favored informational policy tools, they often lack effectiveness. Studies have identified the prevalence of an attitude – action gap, and showed that structural constraints, such as information asymmetries and overflow as well as restrictions on time and other relevant resources by consumers, have prevented informational policy instruments from achieving major changes in food consumption patterns (Fuchs *et al.,* 2016; Horne, 2009). Among private certification schemes, those with the largest market shares often have little actual impact on the sustainability characteristics of a food product, as they tend to emphasize documentation rather than performance or fail to tackle the most impactful aspects of food production, distribution and consumption (Fuchs & Boll, 2012; Kalfagianni & Fuchs, 2015). Simultaneously, studies inquiring into the drivers of meat consumption have highlighted its promotion via advertising and media images that transport images of identity (especially masculinity, but also national and cultural identity) as well as artificially low meat prices (Bogueva *et al.,* 2017).

Thus, policy efforts to improve the sustainability of food consumption in general, and reduce animal protein consumption in particular, would require a policy mix reaching far beyond the (nudging of the) individual consumer (Fuchs *et al.,* 2013, 2016; Glanz & Mullis, 1988; Wolf & Schönherr, 2011). Such policies would need to focus on regulating the advertising of animal products, as well as sources of low meat prices, among others through lowering subsidies and enhancing (implementation of) animal welfare, labor and environmental standards. Simultaneously, policies could support (elements of) alternative food systems such as community-supported agriculture and different forms of farmers markets (Hinrichs & Lyson, 2007). Altering current dietary trajectories should not compromise the needs of low-income populations and of IPLCs and will face significant cultural and psychological barriers (Kuhnlein *et al.,* 2006; Whitley *et al.,* 2018).

Reducing food waste

Food waste currently runs at ~30-40% of all food production in developing and developed countries alike (Gustavsson *et al.,* 2011; Bond *et al.,* 2013; FAO, 2015, 2017; Bellemare *et al.,* 2017). Causes and hence possible solutions differ geographically, and they include more effective pest control (Oerke, 2006; Oliveira *et al.,* 2014), improved food distribution and better food storage in developing regions (Sheahan & Barrett, 2017), and consumer education (Kallbekken & Saelen, 2013; Aschemann-Witzel *et al.,* 2017; Young *et al.,* 2017) and less wasteful marketing practices in developed countries (Garrone *et al.,* 2014; Halloran *et al.,* 2014; Rezaei & Liu, 2017). Some countries, such as Japan, South Korea, Taiwan and Thailand have established operating systems that safely recycle more than one-third of their food waste as animal feed (Menikpura *et al.,* 2013; zu Ermgassen *et al.,* 2016; Salemdeeb *et al.,* 2017). However, several studies suggest an upper bound to feasible reduction in food waste of around 50% (Parfitt *et al.,* 2010; Bajzelj *et al.,* 2014; Odegard & van der Voet, 2014). Cutting food waste will thus require substantial changes in food supply chains and business models (Parfitt *et al.,* 2010; Papagyropoulou *et al.,* 2014; Aschemann-Witzel *et al.,* 2015; Roodhuyzen *et al.,* 2017).

Improving food distribution and localizing food systems

Localization of food systems is advocated by research (Hines, 2000) and by social movements, and has entered policy making at various levels (see e.g., the EU Regulation 1305/2013 on support for rural development or city-level food policies such as in Toronto or Manchester) emphasizing territoriality and sovereignty in food production and consumption. The major arguments supporting short food supply chains (SFSCs), beyond their socio-economic impacts such as revitalization of rural areas and local cultures (Brunori *et al.,* 2016; Schmitt *et al.,* 2017) are their potential to enhance food security and decrease food miles, the latter one addressing land-use change (less physical infrastructure for transportation), climate change (lower CO_2 emissions due to less transportation) and energy use (Mundler & Rumpus, 2012). However, the shortcomings of the local scale are also mentioned in literature, acknowledging that local is not necessarily better in terms of ecological sustainability, health, social justice etc. (Born & Purcell, 2006; Brunori *et al.,* 2016; Recanati *et al.,* 2016; Schmitt *et al.,* 2017). Evidence shows that the ecological impacts of SFSCs can be diverse, depending on the product type, the farming system (Rothwell *et al.,* 2016), the manner of transportation/logistics (Mundler & Rumpus, 2012; Nemecek *et al.,* 2016), the natural resources available locally and the actual social (Recanati *et al.,* 2016), economic and policy context (Leventon & Laudan, 2017).

Positive environmental impacts of SFSCs can be improved if the localization of agricultural production is coupled with: i) closing the loops between production, consumption and waste management (Benis & Ferrão, 2017; Sala *et al.,* 2017) (see also the section on circular economy in

6.4), ii) urban planning (integrating agriculture into the management of urban systems) (Barthel & Isendahl, 2013) through novel technological solutions that enable sustainable but more intensive food production (e.g., vertical gardens) (see also 6.3.5), iii) alternative food distribution options (e.g. social supermarkets or food banks) (Michelini *et al.,* 2018), iv) dietary changes as discussed below (Benis & Ferrão, 2017), and v) novel governance solutions across the food chain that enable more direct engagement of local communities in food production (Sonnino, 2017) and the (re)connection of various types of producers and consumers (Mount, 2012).

Expanding food market transparency and price stability

Food price increases during the 2007-08 world financial crisis resulted in severe impacts on the quality of life in many countries (Ivanic & Martin, 2008; Bellemare, 2015), leading many to assert that policies to increase food market transparency might lead to less volatility (Clapp, 2009; Minot, 2014). Policy responses to price increases have included reductions on food taxes and import tariffs, and increasing subsidies and food-based safety nets, although there is mixed evidence on which policies have been most effective in supporting poor populations (Wooden & Zama, 2010), indicating that social targeting is needed in combination with food support programs.

Public food procurement policies can also play a role in stabilizing price support for farmers. In Brazil, where government expenditures represent 20% of the GDP, two initiatives of public procurement of around US$300 million in expenditures are innovating to merge social and environmental targets. The Food Acquisition Program (created in 2003) and the National Program of School Feeding (created in 2009) have the purpose of: (i) providing healthy and balanced food respecting the culture, values and eating habits, especially for populations in socioeconomic vulnerability, and (ii) supporting the sustainable development of smallholding agriculture by incentives for producing local and seasonal food (Brazil, 2017). While the impact of these programs requires further evaluation, their goals to acquire locally produced food for school consumption while encouraging small-scale agricultural economies can be applicable in different contexts.

6.3.2.2 Sustainably managing multifunctional forests

Expanding and improving community-based forest management and co-management

Community-based forest management has emerged as a promising forest management alternative to state-controlled forest management (Charnley & Poe, 2007; Flint *et al.,* 2008; Krott *et al.,* 2014; Paudyal *et al.,* 2017). Almost one third of the forests in the Global South are now managed by IPLCs **(Figure 6.2)**, more than twice the share of protected areas (Chape *et al.,* 2005; RRI, 2014; Blackman *et al.,* 2017). Global trends towards decentralized management of forests, articulated through the active recognition of IPLCs rights to self-governance, have substantially improved the quality of life of forest-dependent communities, by providing them with greater livelihood benefits (Agrawal *et al.,* 2008; Gautam *et al.,* 2004; Larson & Soto, 2008; Phelps *et al.,* 2010; Duchelle *et al.,* 2014; RRI, 2014, 2016; Lawler & Bullock, 2017) including capital formation, governance reform, community empowerment and societal change (Pokharel *et al.,* 2007, 2015). Expanding and improving of community-based forest management have provided substantial opportunities for the conservation of forest ecosystems (Ostrom & Nagendra, 2006; Chazdon, 2008; Sandbrook *et al.,* 2010; Porter-Bolland *et al.,* 2012; Naughton-Treves & Wendland, 2014; van der Ploeg *et al.,* 2016; Asner *et al.,* 2017; Robinson *et al.,* 2017; Stickler *et al.,* 2017).

Many countries in Asia, such as the Philippines, Vietnam, Indonesia and Thailand have put forward new organizations, authorities and bottom-up approaches to promote community-based approaches to forest management (Sato, 2003; Poffenberger, 2006; Salam *et al.,* 2006; Sunderlin, 2006; Sikor & Tan, 2011), in the light of growing evidence of their effectiveness at contributing to poverty reduction (Ostrom, 1990; Brown *et al.,* 2003; Gautam *et al.,* 2004; Gilmour *et al.,* 2004; Gautam and Shivakoti, 2005; Sunderlin, 2006). These large areas managed by IPLCs do not usually attract financial and other resources akin to that provided for government-managed forest and protected areas. Moreover, there have been challenges in ensuring that communities have the right to benefit from co-management arrangements, such as from the sale of timber (Gritten *et al.,* 2015) and ensuring that IPLCs do not suffer from community forestry arrangements (such as in loss of food security or access to resources) (Sikor & Tan, 2011; Tuan *et al.,* 2017).

Forest titling programs have improved inclusion of settlers and secured alienation rights (Nelson *et al.,* 2001; Ostrom *et al.,* 2002; Pagdee *et al.,* 2006; Jacoby & Minten, 2007; Riggs *et al.,* 2016). However, forest tenure may not change management patterns without supporting the customary institutions of IPLCs that enforce exclusion rules and legitimize claims to them (Place & Otsuka, 2001; Ojha *et al.,* 2009; Kerekes & Williamson, 2010; Gabay & Alam, 2017).

Co-management of forest resources between the state and IPLCs, as well as other stakeholders, has also been promoted as an alternative to centralized governance approaches to achieve socio-economic and environmental objectives in developing countries (Carter & Gronow, 2005;

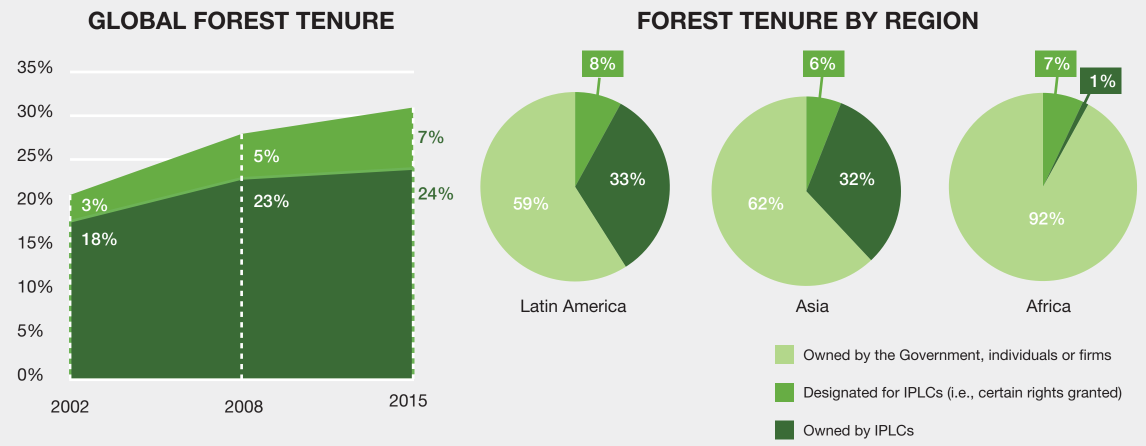

Figure 6 2 **Global patterns of forest owned by and designated for IPLCs.**
Source: RRI (2016).

Kothari *et al.,* 2013; Akamani & Hall, 2015). As forests are common-pool resources from which the exclusion of potential users is difficult, achieving sustainable forest management can be regarded a collective responsibility, especially in developing countries where the government has limited capacity to implement appropriate forest policy and needs support of diverse stakeholders (Sikor, 2006; Ostrom, 2010; Pokharel *et al.,* 2015). In the above context, collaborative governance is an appealing arrangement for sustainable forest management because of its potential to combine strengths of different management approaches and stakeholders (Carter & Gronow, 2005; Fernández-Giménez *et al.,* 2008).

Improving policies relating to PES and REDD+

There has been a rapid expansion in the number of payments for ecosystem services (PES) schemes and projects globally over the past 20 years, and many decision makers, from governments to NGOs, are considering either initial experimentation or continued expansion of PES. There is a great diversity of institutional configurations in PES arrangements, many of which involve a strong role of the state (McElwee, 2012; Shapiro-Garza, 2013). However, the effectiveness of PES approaches is currently unknown, namely because they are interpreted and implemented in many different ways (Borner *et al.,* 2017; Salzman *et al.,* 2018). Overall, the literature indicates that PES approaches are not a panacea (Muradian *et al.,* 2013), due to high preparation and transaction costs, uneven power relations, and distribution of benefits (Porras *et al.,* 2012; Salzman *et al.,* 2018; Berbés-Blásquez, 2016; Cáceres *et al.,* 2016; Van Hecken *et al.,* 2017). In other words, the performance of PES depends not just on economic incentives but also on other factors like motivations and environmental values (Hack, 2010; Hendrickson & Corbera, 2015; Grillos, 2017). Lessons learned from the literature on these economic financing instruments for conservation include the need to have in place strong regulatory frameworks; have clear metrics and indicators; have motivated buyers and sellers of services; recognize pluralistic value systems alongside financial considerations; acknowledge the importance of distributional impacts when designing economic instruments; and recognize that economic approaches are not a panacea (Ezzine-de-Blas *et al.,* 2016; Robalino & Pfaff, 2013; Pascual *et al.,* 2017; Hack, 2010; Hendrickson & Corbera, 2015; Grillos, 2017; van Hecken *et al.,* 2017; Salzman *et al.,* 2018; see also section 6.3.4.5 on watershed PES)

One important PES-like initiative is REDD+ (Reducing Emissions from Deforestation and forest Degradation), part of the negotiations under the UNFCCC since 2005 as a climate mitigation strategy to compensate developing countries for reducing GHG emissions from deforestation and forest degradation. REDD+ also aims to contribute to poverty alleviation of smallholders (through sale of carbon credits or direct forest products) and biodiversity conservation. Carbon forestry projects have expanded particularly rapidly in Latin America (Osborne, 2011; Corbera & Brown, 2010; Rival, 2013) and Africa (Namirembe *et al.,* 2014). However, the literature is currently mixed on the success rates of forest carbon projects in general and REDD+ has faced a number of challenges. These include a lack of a strong financial mechanism to ensure sufficient funding and demand for credits (Turnhout *et al.,* 2017), the high costs involved in setting up REDD+ projects (Luttrell *et al.,* 2016; Bottazzi *et al.,* 2013; Visseren-Hamakers *et al.,* 2012a), meeting the technical requirements of REDD+ (Turnhout *et al.,* 2017; Cerbu *et al.,* 2013) and REDD+'s ability to deliver non-carbon benefits such as biodiversity conservation (Hall *et al.,* 2012; Venter *et al.,* 2013; Duque *et al.,* 2014; Murray *et al.,* 2015) and social livelihoods (Atela *et al.,* 2015; Boyd *et al.,* 2007; Reynolds, 2012; Caplow *et al.,* 2011; Lawlor *et al.,* 2013). REDD+ has also been observed to contribute to a recentralization of forest governance by bringing forests under renewed forms of government control, with potentially negative consequences for nature, NCP and GQL (Ribot *et al.,* 2006; Phelps *et al.,* 2010; Sunderlin *et al.,* 2014; Duchelle *et al.,* 2014; Vijge & Gupta, 2014; Abidin 2015).

The future of REDD+ depends on its ability to safeguard against negative side effects of REDD+ and ensure that forests continue to deliver noncarbon benefits (Chhatre *et al.,* 2012; Visseren-Hamakers *et al.,* 2012b; Tacconi *et al.,* 2013; Luttrell *et al.,* 2013, Ojea *et al.,* 2015). As part of this, REDD+ will need to be inclusive of multiple values and perspectives, including historical, cultural and spiritual values (Gupta *et al.,* 2012; Brugnach *et al.,* 2014). This will require adequate formal arrangements for the participation of IPLCs. This involvement is crucial, since IPLCs control substantial areas of tropical forests (Anon, 2009; Bluffstone *et al.,* 2013). However, arrangements for participation by IPLCs in REDD+ policies are not clear in most country readiness plans for REDD+, despite safeguard guidance from UNFCCC (Ehara *et al.,* 2014), and participation has generally been weak in pilot activities, with many communities only consulted, rather than being involved in a systematic manner in all aspects of REDD+ planning (Hall, 2012; Brown, 2013). There is evidence that projects where IPLCs have been included from the beginning are stronger (Chernela, 2014). There is also potential for inclusion of IPLCs in community-based carbon monitoring, which has proven accurate and low cost (Danielsen *et al.,* 2013; Pratihast *et al.,* 2013; Brofeldt *et al.,* 2014; McCall *et al.,* 2016). See Supplementary Materials 6.2.3 for a detailed discussion on PES and REDD+.

Supporting Reduced Impact Logging (RIL)

More responsible logging practices, such as Reduced Impact Logging (RIL), are options to avoid deforestation and forest degradation. RIL, which involves close planning and control of harvesting operations, has increased in importance in the past decades. Such logging practices lower the ecological impacts of logging, especially on biodiversity (Bicknell *et al.,* 2017; Chaudhary *et al.,* 2016; Martin *et al.,* 2015). For example, in a study in East Kalimantan in Indonesia, application of RIL techniques have been found resulting in nearly half (36 vs 60 trees per ha) of collateral damage of trees as compared to the conventional harvesting methods (Sist, 2000). RIL techniques along with postharvest silvicultural treatments have also been found effective in enhancing canopy tree growth and regeneration and controlling invasion by alien and undesirable species (Campanello *et al.,* 2009). Moreover, improved logging practices in tropical forests can substantially reduce forest carbon loss and enhance retention (Putz *et al.,* 2008).

Promoting and improving forest certification

Forest certification, an economic instrument introduced in the early 1990s to improve forest management, can help address the concerns of deforestation and forest degradation and promote conservation of biological diversity especially in the tropics by promoting sustainable forest management and establishing deforestation-free supply chains (Rametsteiner & Simula, 2003; Auld & Gulbrandsen, 2008; Damette & Delacote, 2011). For instance, certification has been found to have positive impacts in terms of ecological outcomes (forest structure, regeneration, and lower fire incidences) (Kalonga *et al.,* 2015; Pena-Claros *et al.,* 2009) and biodiversity conservation in some places (Van Kuijk *et al.,* 2009; Kalonga *et al.,* 2016). Positive social impacts, such as better working and living conditions, active local institutions for discussions among the forestry company and local communities, and benefit sharing have also been documented (Cubbage *et al.,* 2010; Cerutti *et al.,* 2014; Burivalova *et al.,* 2016). There has also been criticism of different certification schemes, and forest certification more generally, among others on the fact that most certified forests are in the global North, instead of the South (Rametsteiner & Simula, 2003), in part due to the technical and financial demands for becoming certified can represent a hurdle for small and medium-sized enterprises in the South. For instance, current certification schemes tend to favor large forestry operations and do not directly translate to smaller operations. While there is still limited evidence of the impacts of different forest certification schemes (Visseren-Hamakers & Pattberg, 2013), improved assessment practices are suggesting ways forward (van de Ven and Cashore, 2018).

Controlling illegal logging

Illegal logging, which can be viewed as a symptom of failure of governance and law enforcement, is a major problem in achieving sustainable forest management in many countries, particularly forest-rich developing countries (Brack & Buckrell, 2011). Forest dependent poor people are the most harmed by illegal logging while powerful economic groups benefit the most from it (ODI, 2004). International trade in illegally logged timber is an important factor associated with this problem (Brack & Buckrell, 2011). In recent years, however, consumer countries have been paying increasing attention to trade in illegal timber and have taken different measures to exclude illegally produced timber from the market. The European Union's Action Plan for Forest Law Enforcement, Governance and Trade (FLEGT), published in 2003, is an example of such measures. The FLEGT regulations and approaches have often been combined with improved management of concessions in countries participating in FLEGT through Voluntary Partnership Agreements with the EU (Tegegne *et al.*, 2014). Apart from the European Union's Timber Regulation 995/2010, some other countries, including Australia, Indonesia, Japan and USA, have their own law to control illegal logging (Hoare, 2015).

Monitoring and regulating forest use

The development and availability of transparent forest monitoring data is a major step to establish and improve the forest sector (Fuller, 2006). By identifying the extent of deforestation on a regular basis, decision makers have the option to coordinate actions, prioritize areas and develop policies to reduce forest losses. In the Brazilian Amazon, where the deforestation was substantially reduced from 2004 to 2017 (INPE, 2017), the understanding of forest change patterns was essential to allocate public resources and to provide the first reaction to the illegal processes that were leading to deforestation in that region. The monitoring systems have been improved to the point of offering daily real-time data, constituting one of the most important tools for the fight against deforestation in Brazil (Nepstad *et al.,* 2014; Assunção *et al.,* 2015). Also, global initiatives like the Global Forest Watch are supporting national and sub-national governments to implement national law (as in the case of the law Nr 26331on "Minimum Standards of Environmental Protection of Native Forests" in Argentina), as well as civil society and private sector engagement in forest monitoring and conservation (FAO, 2015; GFW, 2017). Reforestation projects have contributed to reversing the deforestation trend and increasing forest cover in some countries (Supplementary Materials 6.2.3). Especially REDD+ and PES schemes have contributed to expand reforestation and afforestation projects in recent years (Carnus *et al.,* 2006; Madsen *et al.,* 2010). REDD+ projects have expanded particularly rapidly in Latin America (Osborne, 2011; Corbera & Brown, 2010; Corbera & Brown, 2008) and Africa (Jindal *et al.,* 2012; Namirembe *et al.,* 2014).

Land tenure recognition and cadastral registers are tools that contribute to the implementation of regulations aimed to protect forest and support reforestation actions. For instance, the Rural Environmental Registry (CAR) in Brazil records and analyses information about land use and environmental compliance in all private properties. CAR registration is mandatory and linked to official credit support, environmental licensing and regularization. It is also used in voluntary agreements for trading agricultural products and facilitating the process of forest restoration to reach legal compliance (Soares-Filho *et al.,* 2014; Servicio Florestal Brasileiro, 2016). The implementation of the CAR system in Brazil is an example of confronting the simultaneous challenges of monitoring, enforcement and compliance, and reconciling forest and water conservation and other production sectors, particularly agriculture.

Forest concessions can also be an option to protect forest cover and regulate use, reducing the pressure to replace the natural vegetation with other land uses. Concessions give the holder rights, including harvesting timber (or other forest products) and use of forest services (e.g. tourism, watershed protection) (Gray, 2002). Concessions, if properly governed, can be an important instrument to provide economic value to forests and reduce the pressure to replace the natural vegetation with other land uses around the world. Besides employment and revenue creation, forest concessions may reinforce the presence of the state and improve the rights over land tenure (FAO, 2015). Concessions are also a good governance tool for the state, considering the establishment of conditions and compensation, such as the development of local services (schools, medical assistance, security) and infrastructure (water supply, transport, roads, bridges). This instrument can be applied not only by entrepreneurs and companies, but also by IPLCs with different land tenure regimes (van Hensbergen, 2016). Poorly governed concession schemes, however, can drive deforestation and marginalize local communities. Governments can enhance the contributions of forest concessions by requiring participatory planning, long-term sustainable forest management, and control of illegal logging.

Problems of forest concessions in tropical countries are related to weak local governance, poor level of compliance, difficulties with monitoring and traceability systems, low technical capacity of managing the forest, and insufficient rewards for sustainable forest management in the global timber market (Azevedo-Ramos *et al.,* 2015; van Hensbergen, 2016; Segura-Warnholtz, 2017). Therefore, forest concessions are often regarded drivers of forest degradation (PROFOR, 2017). Corruption in attaining timber concessions is another problem associated with this instrument, especially in developing countries. There are initiatives of implementing monitoring and traceability systems, but it is important to manage the bureaucracy and additional transaction costs that may deter potential investors (Azevedo-Ramos *et al.,* 2015).

6.3.2.3 Protecting nature within and outside of protected areas

Improving management of protected areas

There is a large literature that has evaluated the performance of protected areas (PAs) in halting biodiversity loss and securing ecosystem services into the future, showing mostly positive (albeit moderate) conservation outcomes (Carranza *et al.,* 2014; Barnes *et al.,* 2016; Eklund *et al.,* 2016; Gray *et al.,* 2016). However, research also points to substantial shortfalls in PA effectiveness around the world (Laurance *et al.,* 2012; Guidetti *et al.,* 2014; Watson *et al.,* 2014; Geldmann *et al.,* 2015, 2018; Schulze *et al.,* 2018). Poor PA performance is attributed to management deficiencies related to inadequate resources and weak governance. It also includes low compliance due to inhibited local access to important resources (Stoll-Kleemann, 2010; Bennett & Dearden, 2014; Bruner *et al.,* 2001; Eklund & Cabeza, 2016; Leverington *et al.,* 2010; Watson *et al.,* & Hockings, 2014). Evidence shows that improving PA effectiveness depends on enforcing sound management (Juffe-Bignoli *et al.,* 2014), monitoring (Schulze *et al.,* 2018) and adequate resourcing (McCarthy *et al.,* 2012). Using robust methods, such as those available via the global Protected Areas Management Effectiveness (PAME) initiative, controlling potential bias, and integrating data on ecological outcomes (e.g. temporal and spatial counterfactual analysis) and social indicators could make the assessment of PA effectiveness more systematic and comparable across spatial and temporal scales, addressing the needs of different decision makers more effectively (Coad *et al.,* 2015; Eklund *et al.,* 2016; Stoll-Kleemann, 2010; Watson *et al.,* 2016) for all decision makers.

PAs generate multiple benefits to both local and distant populations (Chan *et al.,* 2006; Ceausu *et al.,* 2015; Egoh *et al.,* 2011; Larsen *et al.,* 2012; Schröter *et al.,* 2014a), and provide fundamental contributions such as protecting watersheds, buffering extreme events, regulating local climate, harboring biodiversity, and providing spaces of emotional, social and spiritual fulfilment. Protected areas and these multiple contributions also have associated costs in limiting and regulating land uses and forms of access to resources (Birner & Wittmer, 2004; Holzkamper & Seppelt, 2007; Wätzold *et al.,* 2010; Wätzold & Schwerdtner, 2004; Nalle *et al.,* 2004). Balancing the benefits and costs of PAs across different stakeholders can increase the management effectiveness of PAs (see also Supplementary Materials 6.2.4). Options include co-management governance regimes (i.e. sustainable-use PAs), which engage communities in maintaining cultural and livelihood benefits (Oldekop *et al.,* 2016), and jointly consider approaches to mitigating conflicts and managing trade-offs. PA effectiveness can also be enhanced by supporting local households to establish or find alternative livelihood and income options (i.e., improving options and capabilities; Neudert *et al.,* 2017), supporting benefit-sharing mechanisms that eliminate inequalities (Swemmer *et al.,* 2017) and securing the availability of financial resources to support these measures for a sufficiently long period to ensure sustainability (Wätzold *et al.,* 2010).

Improving spatial and functional connectivity of PAs

The functionality of PA networks cannot be maintained when the habitat area is too small and fragmented, and when the landscape beyond PA boundaries is inhospitable (Bengtsson *et al.,* 2003). PAs then become islands of biological conservation (Bauer & Van Der Merwe, 2004; Crooks *et al.,* 2011; Seiferling *et al.,* 2012; Barber *et al.,* 2014; Wegmann *et al.,* 2014) threatening the long-term viability of their biodiversity, especially many wildlife populations (DeFries *et al.,* 2005; Newmark, 2008; Riordan *et al.,* 2015). There are also significant geographic and ecological biases in the representation of habitats and ecosystems in PAs (e.g., Pressey *et al.,* 2003; Joppa & Pfaff, 2009, Butchart *et al.,* 2012, 2015), which result in unplanned assemblages of PAs confined to economically unproductive areas (Scott *et al.,* 2001; Evans, 2012), with little ecological relevance (Opermanis *et al.,* 2012), which ultimately compromise their overall conservation potential (Watson *et al.,* 2014).

Options to address these challenges include several policy support tools for (spatial) conservation prioritization to inform where to establish new PAs so that more biodiversity is conserved in a cost-effective way, accounting for multiple competing sea- or land uses and socioeconomic factors (e.g., Dobrovolski *et al.,* 2014; Forest *et al.,* 2007; Isaac *et al.,* 2007; Montesino Pouzols *et al.,* 2014; Nin *et al.,* 2016; Di Minin *et al.,* 2017). Spatial conservation planning can be a useful tool for enhancing landscape connectivity, maximizing the ecological representation of PA networks and safeguarding Key Biodiversity Areas (Edgar *et al.,* 2008; Krosby *et al.,* 2010, 2015; Dawson *et al.,* 2011; Cabeza, 2013; Dickson *et al.,* 2014, 2017; Kukkala *et al.,* 2016; Watson *et al.,* 2016; Saura *et al.,* 2018). Research has estimated that only 19.2% of the ~15,000 Key Biodiversity Areas identified around the world are fully protected, and that the proportion of the PAs comprising these areas is decreasing over time (Butchart *et al.,* 2012; UNEP-WCMC & IUCN, 2016). Therefore, protected areas are being disproportionately established in areas that are suboptimal from a biodiversity conservation point of view (Butchart *et al.,* 2012, 2015). Shifting PA establishment to focus on Key Biodiversity Areas is thus an important policy priority to reverse extinction risk trends.

Building on the expansion of PAs under Aichi Biodiversity Target 11, the next phase of global biodiversity targets offers an excellent opportunity to correct some of the geographic biases of establishing PAs in recent decades, often based on local and opportunistic criteria (Pressey *et al.,* 2003; Joppa & Pfaff, 2009; Lewis *et al.,* 2017). Especially the conservation of world's old-growth forests can be addressed in Multilateral Environmental Agreements, as targets for PA expansion (e.g., Watson *et al.,* 2018). Expanding PAs requires managing trade-offs among societal objectives, and improvement can be achieved with global coordination (DeFries *et al.,* 2007; Polasky *et al.,* 2008; Faith, 2011; Venter *et al.,* 2014) and consultation of different stakeholders.

Improving transboundary PA and landscape governance

Options to enhance PA effectiveness also need to address conservation planning and management at broader geographic scales (van Teeffelen *et al.,* 2006; Le Saout *et al.,* 2013; Kukkala *et al.,* 2016). Transboundary conservation planning is essential to improve the global status of biodiversity (Erg *et al.,* 2012; Pendoley *et al.,* 2014; Dallimer & Strange, 2014; Lambertucci *et al.,* 2014), particularly for wide-ranging species that cannot be conserved within political boundaries, such as large carnivores (Wikramanayake *et al.,* 2011; Wegmann *et al.,* 2014; Santini *et al.,* 2016; Di Minin *et al.,* 2017), species that migrate (Flesch *et al.,* 2010; Runge *et al.,* 2015; Owens, 2016) and species that might shift their range in response to climate change (Wiens *et al.,* 2011; Zimbres *et al.,* 2012; Johnston *et al.,* 2013; Pavón-Jordán *et al.,* 2015).

Research shows that setting conservation targets in a spatially coherent manner beyond national borders is vital for improving the effectiveness of PA networks (van Teeffelen *et al.,* 2015; Wegmann *et al.,* 2014). Different works have demonstrated a major efficiency gap between national and global conservation priorities, finding that if each country sets its own conservation priorities without international coordination, more biodiversity is lost than if conservation decision-making is done through international partnerships and globally coordinated efforts (Montesino-Pouzols *et al.,* 2014; Santini *et al.,* 2016). The European Union's Natura 2000 network of PAs provides an illustrative example of joint initiatives crossing political and national boundaries. With more than 27,000 sites across all EU countries, covering over 18% of the EU's land area and almost 6% of its marine environments, Natura 2000 is the most expansive coordinated network of PAs in the world (Milieu *et al.,* 2016). It is the cornerstone of the EU's Biodiversity Strategy to 2020, and one of the largest policy efforts in conserving biodiversity irrespective of national and political boundaries. A plethora of research studies has evidenced the overall ecological effectiveness of Natura 2000, with a special emphasis on terrestrial vertebrates and threatened habitats (Gruber *et al.,* 2012; Pellissier *et al.,* 2013; Kolecek *et al.,* 2014; Sanderson *et al.,* 2016; Beresford *et al.,* 2016; Milieu *et al.,* 2016). The Greater Mekong Subregion Biodiversity Conservation Corridors Project or the Mesoamerican Biological Corridor are also key initiatives illustrating the importance of transboundary conservation planning at the landscape level (ADB, 2011; Mendoza *et al.,* 2013; Crespin & García-Villalta, 2014). Policy options to promote transformative change towards sustainability in the Arctic include the application of new, multi-sector frameworks for integrated ecosystem management (Pinsky *et al.,* 2018), the establishment of a circumpolar network of Protected Areas (Fredrikson, 2015) and the proposal for the creation of a global Arctic sanctuary in the high seas (European Parliament, 2014; Greenpeace, 2014).

Recognizing management by IPLCs and OECMs

The conservation of a substantial proportion of the world's biodiversity and NCP largely depends on the customary institutions and management systems of IPLCs (Maffi, 2005; Gorenflo *et al.,* 2012; Gavin *et al.,* 2015; Renwick *et al.,* 2017; Garnett *et al.,* 2018). Evidence suggests that IPLCs are able to develop robust institutions to govern their land- and seascapes in ways that align with biodiversity conservation (ICC, 2008, 2010; Stevens *et al.,* 2014; Ens *et al.,* 2015, 2016; Trauernicht *et al.,* 2015; Blackman *et al.,* 2017; Schleicher *et al.,* 2017). These customary institutions and management systems are based on locally-grounded knowledge and encoded in complex cultural practices, relational values, usufruct systems, spiritual beliefs, kinship-oriented philosophies, and principles of stewardship ethics (Berkes *et al.,* 2000; Bird, 2011; Gammage, 2011; Kohn, 2013; Walsh *et al.,* 2013; Trauernicht *et al.,* 2015; Gaudamus & Raymond-Yakoubian, 2015; Fernández-Llamazares *et al.,* 2016; Renwick *et al.,* 2017).

Formal recognition of IPLC rights over their territories can be an effective means to significantly slow habitat loss (Nepstad *et al.,* 2006; Soares-Filho *et al.,* 2010; Ricketts *et al.,* 2010; Porter-Bolland *et al.,* 2012; Nolte *et al.,* 2013; Paneque-Gálvez *et al.,* 2013; Ceddia *et al.,* 2015; Blackman *et al.,* 2017). The growing recognition of governance diversity in global environmental policy offers numerous opportunities for sound management of nature and its contributions to the larger society (Berkes, 2009; Kothari *et al.,* 2012; Ruiz-Mallén & Corbera, 2013; Nilsson *et al.,* 2016), while improving the quality of life of IPLCs, including addressing some of the human rights violations associated with the establishment and governance of some PAs (e.g., Brockington & Igoe, 2006; Goldman, 2011; Kohler & Brondizio, 2016). Certain strict PAs have induced displacements and exclusion of IPLCs (West *et al.,* 2006; Mascia & Claus, 2008; Curran *et al.,* 2009; Agrawal & Redford, 2009; Brockington & Wilkie, 2015), undermining food sovereignty (Golden *et al.,* 2011; Foale *et al.,* 2013; Nakamura & Hanazaki, 2016; Sylvester *et al.,* 2016) and contributing to psychological distress and trauma (Dowie, 2009; Zahran *et al.,* 2015; Snodgrass *et al.,* 2016).

A crucial breakthrough in conservation paradigms over the last decades has been the emergence and growing awareness of a number of IPLC-centred designations to conservation, including co-management regimes, community-based conservation areas, integrated conservation and development projects, sacred natural sites, Indigenous Community Conserved Areas (ICCAs), and biocultural approaches to conservation (e.g., Berkes, 2004, 2007, 2009; Folke *et al.,* 2005; Armitage *et al.,* 2007;

Kothari *et al.,* 2013; Brooks *et al.,* 2013; Gavin *et al.,* 2015; Alexander *et al.,* 2016; Berdej & Armitage, 2016; Sterling *et al.,* 2017). Many of these approaches will contribute a substantial share of the world's "Other Effective Area-Based Conservation Measures" (OECMs) such as proposed under Aichi Target 11 (Jonas *et al.,* 2014, 2017; Laffoley *et al.,* 2017; Garnett *et al.,* 2018).

Sacred natural sites, as a specific example of OECMs, are areas of land or water that have spiritual values to certain IPLCs (Thorley & Gunn, 2007; Ormsby, 2011). They contribute to the conservation of diverse habitats and species as well as traditional land use practices (Salick *et al.,* 2007; Metcalfe *et al.,* 2009; Gavin *et al.,* 2015; Samakov & Berkes, 2017). Their governing institutions are diverse, including informal norms, rules and taboos passed on by generations (Anthwal *et al.,* 2010; Bhagwat & Rutte, 2006b; Bobo *et al.,* 2015; Ya *et al.,* 2014), and are under increasing pressure from globalization (Bhagwat & Rutte, 2006; Virtanen, 2002; Domínguez & Benessaiah, 2015; Fernández-Llamazares *et al.,* 2018). Sacred natural sites have been combined with legal and economic instruments, often with controversial results (Bhagwat & Rutte, 2006b; Brandt *et al.,* 2015). Appropriate legal recognition of sacred natural sites has been deemed as a critical factor to ensure their effectiveness in conserving nature and NCP (Davies *et al.,* 2013; Smyth, 2015; Mwamidi *et al.,* 2018). Specific legal recognition of sacred natural sites builds on prior broader recognition of collective IPLC tenure rights and self-determination (Kothari, 2006; Berkes, 2009; Almeida, 2015; Borrini-Feyerabend & Hill, 2015). However, there is evidence that top-down forms of recognition, without consultation often undermine local initiative and grassroots action (Borrini-Feyerabend *et al.,* 2010; Kothari *et al.,* 2013). Best practice cases indicated that knowledge-sharing and mutual learning are key success factors when sacred sites are recognized as OECMs (Aerts *et al.,* 2016b; Irakiza *et al.,* 2016; Jonas *et al.,* 2018).

Addressing the Illegal Wildlife Trade (IWT)

Despite intense worldwide efforts, the Illegal Wildlife Trade (IWT) still represents a major threat to endangered species. Research shows the major strengths and weaknesses of efforts to address the IWT. CITES currently lacks a global enforcement agency to oversee compliance, which has been argued to compromise its overall effectiveness (Phelps *et al.,* 2010; Heinen & Chapagain, 2002; Oldfield, 2003; Zimmerman, 2003; Reeve, 2006; Toledo *et al.,* 2012; Challender *et al.,* 2015). Further, CITES enforcement within countries is often sporadic at best, with many developing countries lacking the knowledge and identification facilities to help control and report illegal trade (Zhang *et al.,* 2008; Shanee, 2012). The International Consortium on Combating Wildlife Crime (ICCWC) has helped in providing support to countries in the fields of policing, customs, prosecutions and the judiciary, (e.g., through the creation of the ICCWC Wildlife and Forest Crime Analytical Toolkit; UNODC, 2012) and informing IWT decision-making (Nellemann *et al.,* 2014; Sollund & Maher, 2015). In the meantime, research shows that intergovernmental initiatives at the regional level, such as the ASEAN Wildlife Enforcement Network, including 10 Southeast Asian countries, and EU-TWIX, an online forum and database on IWT patterns within the European Union, are also essential for assisting national law enforcement agencies in detecting and monitoring IWT across national borders (Rosen & Smith, 2010; Sollund & Maher, 2015). Civil society and NGO support, such as through TRAFFIC, has been essential for many countries to keep their mandatory reporting requirements for CITES up to date (Reeve, 2006).

Some studies are examining where resources could best be prioritized for improved protected area management and law enforcement, as well as to disrupt shipping routes of IWT (Kiringe *et al.,* 2007; Plumptre *et al.,* 2014; Ihwagi *et al.,* 2015; Patel *et al.,* 2015; Tulloch *et al.,* 2015; Lindsey *et al.,* 2017). Improving detection capacity for "invisible" wildlife trades, through improved data, capacity-building and implementation of innovative technologies such as DNA barcoding and stable isotope analysis, is often cited as a global priority for IWT control (Phelps *et al.,* 2010; Nijman & Nekaris, 2012; Phelps & Webb, 2015; Symes, 2017).

Prioritization of IWT in criminal justice systems has generally led to more effective law enforcement responses (Lowther *et al.,* 2002; Sollund & Maher, 2015; EIA, 2016; Jayanathan, 2016). Similarly, increases in anti-poaching patrols in protected areas generally leads to significant declines in levels of poaching (Dobson & Lynes, 2008; Jachmann, 2008; Fischer *et al.,* 2014; Critchlow *et al.,* 2016; Henson *et al.,* 2016; Moore *et al.,* 2017). Implementing measures to combat corruption among rangers, crime investigators and other relevant officials and civil servants, is also deemed critical to halt IWT (Smith & Walpole, 2005; Bennett, 2015; UNODC, 2016). Also, IPLCs are important allies in global efforts to combat IWT on the ground (Roe, 2011; MacMillan & Nguyen, 2013; Ihwagi *et al.,* 2015; Cooney *et al.,* 2016; Humber *et al.,* 2016; Benyei *et al.,* 2017; Biggs *et al.,* 2017; Massé *et al.,* 2017; Roe *et al.,* 2017), although they often suffer from blanket hunting bans established at local levels that do not discriminate between endangered and common animals (McElwee, 2012) as well as use of trade bans to address other threats such as climate change (Weber *et al.,* 2015). Similarly, both NGO and research presence have been shown to deter wildlife poaching, particularly in areas with minimal governmental surveillance (Hohman, 2007; Pusey *et al.,* 2007; Campbell *et al.,* 2011; N'Goran *et al.,* 2012; Laurance, 2013; Mohd-Azlan & Engkamat, 2013; Daut *et al.,* 2015; Piel *et al.,* 2015; Sollund & Maher, 2015; Tagg *et al.,* 2015).

Finally, well-targeted, species-specific and evidence-based demand reduction policy interventions for illegally-sourced wildlife and its products are also growing in scope and extent, on the understanding that legally-sourced products are managed sustainably based on CITES non-detriment findings, and harvested and traded in accordance with national and international laws (CITES, 2017; Moorhouse *et al.,* 2017). Social marketing strategies (e.g. discouraging rhino horn consumption in Vietnam through TV ads with celebrities) coupled with broad outreach and educational campaigns, are a common strategy to change consumer behaviour (Drury, 2009, 2011; Dutton *et al.,* 2011; Gratwicke *et al.,* 2008a; Veríssimo *et al.,* 2012; Challender & MacMillan, 2014; TRAFFIC, 2016; Truong *et al.,* 2016), although evidence on the effectiveness of such policies is still virtually lacking (MacMillan & Challender, 2014; Challender *et al.,* 2015). Regular online monitoring of e-commerce platforms, websites and social media offers substantial opportunities for the enforcement of IWT regulations (Izzo, 2010; Hansen *et al.,* 2012; Lavorgna, 2015; TRAFFIC, 2015).

Improving Sustainable Wildlife Management (SWM)

Sustainable Wildlife Management (SWM) is an essential tool to conserve wildlife while considering the socioeconomic needs of human populations, including IPLCs (Gillingham & Lee, 1999; Spiteri & Nepal, 2006; Pailler *et al.,* 2015; Riehl *et al.,* 2015; Campos-Silva & Peres, 2016) and the generation of multiple contributions to people (Holmlund & Hammer, 1999; Díaz *et al.,* 2005; Kremen *et al.,* 2007; Whelan *et al.,* 2008, 2015; Kunz *et al.,* 2011; Moleón *et al.,* 2014; Ripple *et al.,* 2014; Poufoun *et al.,* 2016). Several best practices in fostering SWM (e.g., mitigating human-wildlife conflicts) have emerged over the last decades (Brooks *et al.,* 2013; FAO, 2016; Nyhus, 2016), and the debate increasingly includes animal welfare aspects, among others under the heading of "compassionate conservation" (Bekoff, 2013).

Both *incentive-driven* and *financial compensation* schemes can contribute widely to nature conservation and benefit sharing with IPLCs and provide economic compensation for those bearing most of the costs of maintaining public benefits associated with biodiversity conservation (Naughton-Treves *et al.,* 2003; Maclennan *et al.,* 2009; Persson *et al.,* 2015; Dhungana *et al.,* 2016, Supplementary Materials 6.2.4). However, the effectiveness of wildlife compensation schemes in conserving nature and contributing to local quality of life varies (Boitani *et al.,* 2010; Ravenelle & Nyhus, 2017). Some works show that wildlife compensation schemes can reduce conflict (Zabel & Hom-Müller, 2008), reduce wildlife killings (Okello *et al.,* 2014) and recover wildlife populations (Persson *et al.,* 2015), particularly in contexts where IPLCs are facing acute subsistence needs or with wildlife that imposes disproportionate costs. However, several pitfalls and operational issues undermine the effectiveness of wildlife compensation payments mostly related to their administration, including crowding-out effects, unequal distribution of benefits, elite capture, corruption or leakage (e.g., Bulte & Rondeau, 2005; Ogra & Badola, 2008; Spiteri *et al.,* 2008; Agarwala *et al.,* 2010; Uphadyay, 2013; Anyango-Van Zwieten, *et al.*, 2015). Also, some authors have questioned their financial sustainability in the long-term (Nyhus *et al.,* 2003; Bulte & Rondeau, 2005; Swenson & Andrén, 2005; Bauer *et al.,* 2015). In general, research highlights that wildlife compensation schemes are not a silver-bullet solution, although they might be indeed valuable in certain contexts and under certain conditions (Haney, 2007; Dickmann *et al.,* 2011; Ravenelle & Nyhus, 2017). *Conservation performance payments*, conditional on specific conservation outcomes (e.g., bird breeding success), have been argued to partially address some of the operational challenges of incentives focusing on compensation for losses to predation (Zabel & Holm-Müller, 2008).

Nature-based tourism is another revenue-generating use of certain wildlife that can provide incentives for IPLCs to conserve biodiversity in appropriate contexts (Bookbinder *et al.,* 1998; Kiss, 2004; Hearne & Santos, 2005; Lindsey *et al.,* 2005; Lai & Nepal, 2006; Stronza, 2007; Osano *et al.,* 2013). IPLCs with economically viable ecotourism programs linked to wildlife are likely to steer SWM (Stem *et al.,* 2003; Krüger, 2005; Clements *et al.,* 2010; Mendoza-Ramos & Prideaux, 2017), but only when benefits are culturally-appropriate and equitably distributed (Bookbinder *et al.,* 1998; Naidoo & Adamowicz, 2005; He *et al.,* 2008), land tenure is secured (Charnley, 2005; Haller *et al.,* 2008; Bluwstein, 2017), the social and political justice aspirations of IPLCs are respected (Stronza & Gordillo, 2008; Coria & Calfucura, 2012), and the value conflicts introduced by tourism development are fully addressed (Lai & Nepal, 2006; Waylen *et al.,* 2010).

Although financial benefits to sustain SWM have often been prioritized (Tisdell, 2004; Ogra & Badola, 2008), incentives to engage IPLCs in SWM can also include education, empowerment and opportunities for capacity development (Nabane & Matzke, 1997; Brooks *et al.,* 2009), social services and infrastructure (Spiteri & Nepal, 2006), as well as devolution of IPLC rights to manage, and benefit from, wildlife conservation (Lindsey *et al.,* 2009; Western *et al.,* 2015; Nilsson *et al.,* 2016). Moreover, engaging women in SWM as direct beneficiaries and key stewards of wildlife can help bridging the agendas of gender equality and SWM, particularly within the framework of the SDG (Nabane & Matzke, 1997; Espinosa, 2010; Staples & Natcher, 2015; FAO, 2016; UNEP, 2016; Leisher *et al.,* 2016; Lelelit *et al.,* 2017). Gender mainstreaming approaches are crucial for the success of community-based SWM (Ogra, 2012; Meola, 2013; UNESCO, 2016; Davies *et al.,* 2018).

Manage invasive alien species through multiple policy instruments

There are more than 40 international legal instruments dealing with the issue of invasive alien species (IAS), including CITES and the Ramsar Convention on Wetlands, as well numerous national laws. However, there are many legal, institutional and social barriers to effective invasive species management, including information management challenges, resourcing, risk perception and lack of public support, and definitional and jurisdictional issues that can generate a lack of coherent, systemic and community-partnered approach to IAS management. This is particularly the case in urban and peri-urban areas where rapid urban growth and sprawl occurs (Martin *et al.,* 2016; Le Gal, 2017; Riley, 2012; Vane and Runhaar, 2016). Further, low economic incentives to engage private landowners can undermine the effectiveness of the frameworks for IAS management and biodiversity protection (Martin *et al.,* 2016). Developing and implementing IAS management strategies in collaboration with IPLCs has been suggested as an effective means to enhance local capacity to prevent, detect and eradicate IAS in areas inhabited or managed by IPLCs, although the evidence still lies on weak empirical footing, with only a few case-based studies available (e.g., Hall, 2009; Dobbs *et al.,* 2015). It is well established that social, political and economic values, as well as cultural worldviews have been shown to underlie the perception of IAS, as well as preferences over management options (O'Brien, 2006; Warren, 2007; Hall, 2009; Crowley *et al.,* 2017). In view of this, direct inclusion of IPLCs on deliberations over IAS management decisions can help to identify the most strategic and effective measures for IAS control, as well as to anticipate conflict and foster dialogue over different values in inclusive ways (Robinson *et al.,* 2005; Bhattacharyya *et al.,* 2014).

Potential solutions include treating IAS as a collective action problem rather than a private landowner problem (Martin *et al.,* 2016; Graham *et al.,* 2016; Graham, 2013; Howard *et al.,* 2016), implementing projects for removal of IAS through direct payments (Bax *et al.,* 2003; McAlpine at al., 2007; Rumlerova *et al.,* 2016; Brown *et al.,* 2016), through tax incentives combined with restoration work and tradeable permits (see examples in Supplementary Materials 6.2.4).

6.3.2.4 Expanding ecosystem restoration projects and policies

Ecological restoration is *the process of assisting the recovery of an ecosystem that has been degraded, damaged,* or destroyed (SER, 2004) and reforestation can have potential positive impacts to help ecosystems adjust to climate change, such as through restoring altered hydrological cycles, extending habitat for species threatened by climate change, or protecting coastal areas from storms and sea level rise (Locatelli *et al.,* 2015). For instance, the UN is committed to restoration through projects such as reforestation for carbon sequestration (e.g. REDD+) (Nellemann & Corcoran, 2010; Watson *et al.,* 2000; Munasinghe & Swart, 2005) or restoring wetlands for flood protection. There is wide agreement on the importance of expanding restoration efforts, including the CBD Aichi Target 15 that commits to restoration of at least 15% of degraded ecosystems by 2020, the European Union Biodiversity Strategy Target 2, and the Bonn Challenge to restore 150 and 350 million hectares of the world's deforested and degraded lands by 2020 and 2030, respectively. Restoration and reforestation of 12 million ha of forests by 2030 are also key elements of the implementation of the Brazilian Nationally Determined Commitments (NDC) of the Paris Agreement.

Restoration projects make use of both regulatory and market instruments in policy mixes, such as public financing, mitigation banking or offsetting, tax incentives, and performance bonds (Hallwood, 2006; Reiss *et al.,* 2009; Robertson, 2004; Ruhl *et al.,* 2009). Tax incentives for set-asides for restoration work, such as Landcare & Bushcare policies (in Australia), are farmer voluntary policies that encourage community-based strategic restoration projects (Compton and Beeton, 2012), including bush set-asides for recovery from grazing and grants to replant and fence off bushland. Farmers pay for at least half the restoration costs, which can be reclaimed through tax incentives (Abensperg-Traun *et al.,* 2004). The Working for Water Program in South Africa is an example of an approach that combines IAS removal and restoration through targeted employment and payments to poorer participants. The project has been credited with success in native vegetation species recovery (Beater *et al.,* 2008; van Wilgen & Wannenburgh, 2016) and increasing water yields (Le Maitre *et al.,* 2000, 2002; Dye & Jarmain, 2004). Lessons from the South Africa program include the need for continuous monitoring and frequent follow-up, the need to train personnel, and the need for active restoration (and replanting) of native tree species on cleared plots. Another national example of integrating restoration objectives into specific policies is that of the Rural Environmental Registry (CAR), which supports the implementation of the new Forest Law in Brazil (see section on Monitoring and regulating forest use above).

Contextual and historical legacies often shape restoration practices. Therefore, there is increasing recognition that restoration projects need to be seen as part of larger social-ecological systems (Dunham *et al.,* 2018; Zingraff-Hamed, 2017), also considering social goals in the planning, decision-making, implementation and success evaluation of such projects (Junker, 2008; Hallett *et al.,* 2013; Higgs, 2005; Burke & Mitchell, 2007; Woolsey *et al.,* 2005;

2007). It is for example increasingly recognised that it is beneficial to involve all relevant stakeholder groups to gain acceptance (Junker *et al.,* 2007) and to promote social and environmental learning (Pahl Wostl, 2006; Restore, 2013; Petts, 2006). One example is the 're-wilding' approach in the US (Swart *et al.,* 2001; Hall, 2010) to restore to pre-European settlement ecosystems, which contrasts with the cultural landscape approach in Germany (Westphal *et al.,* 2010). The importance of community culture and normative values in shaping social acceptance of restoration projects has often been neglected (Ostergren *et al.,* 2008; Waylen *et al.,* 2009), with acceptance depending on whether restoration builds upon the emotional or cultural attachments that communities have to a place or supports traditional patterns of use (Baker *et al.,* 2014; Buijs, 2009; Drenthen, 2009; Lejon, 2009; Shackelford *et al.,* 2013). Participation, such as through community reforestation, is seen to reduce the risk of conflict (Eden and Tunstall, 2006; Gobster and Barro, 2000; Higgs, 2003) and promises more equitable outcomes, such as access to ecosystem services. This opens restoration as a tool for poverty alleviation. However, there is a knowledge gap in defining measures for social-economic attributes, although this has recently received attention (Baker & Eckerberg, 2016). Overall, there is a need for more research into the realized social and economic outcomes or impacts of restoration (see Supplementary Materials 6.2.4).

Revitalizing ILK and restoring IPLC institutions

Evidence shows that indigenous and local knowledge (ILK) is rapidly changing and eroding in many parts of the world (Cox *et al.,* 2000; Brodt, 2001; Godoy *et al.,* 2005; Brosi *et al.,* 2007; Turner & Turner, 2008; Reyes-García *et al.,* 2007, 2013, 2014; Tang & Gavin, 2016; Aswani *et al.,* 2018). While ILK is inherently dynamic (Berkes, 1999; Gómez-Baggethun & Reyes-García, 2013; Reyes-García, *et al.*, 2016), it has been shown that at least some dimensions of the social-ecological memory of IPLCs are becoming substantially eroded (Ford *et al.,* 2006, 2010; Turvey *et al.,* 2010; Fernández-Llamazares *et al.,* 2015). Rapid social and cultural changes create discontinuity in the transmission of ecological knowledge (Singh *et al.,* 2010; Etiendem *et al.,* 2011; Reyes-García *et al.,* 2010, 2014; Turvey *et al.,* 2010; Shen *et al.,* 2012; Guèze *et al.,* 2015; Luz *et al.,* 2015, 2017), impact the functioning of collective institutions, many of which have supported sustainable resource management and diverse biocultural landscapes for long periods of time (Agrawal, 2001; Oldekop *et al.,* 2013; Fernández-Llamazares *et al.,* 2016, 2018; Sirén, 2017).

Policies focused at revitalizing language and local ecological knowledge also contribute to recognizing and, in some cases, restoring IPLCs' customary institutions for ecosystem management, which have been weakened or eroded (Aikenhead, 2001; McCarter *et al.,* 2014; McCarter & Gavin, 2014; Tang & Gavin, 2016). For example, in contexts where environmental degradation is linked to the loss of cultural values, ILK revitalization efforts have been successfully linked to ecological restoration projects, also providing cultural incentives (Anderson,1996; Long *et al.,* 2003; López-Maldonado & Berkes, 2017; Reyes-García *et al.,* 2018). Some customary education programs have also integrated ILK in school curricula, contributing to strengthen networks of ILK transmission (Kimmerer, 2002; Reyes-García *et al.,* 2010; Ruiz-Mallén *et al.,* 2010; McCarter & Gavin, 2011, 2014; Hamlin, 2013; Abah *et al.,* 2015). Similarly, it has been shown that ILK revitalization efforts are most effective when controlled and managed by the communities involved (Singh *et al.,* 2010; McCarter *et al.,* 2014; Fernández-Llamazares & Cabeza, 2017; Sterling *et al.,* 2017). Moreover, it is important that revitalization efforts consider the gendered nature of knowledge and the crucial role of women in knowledge transmission (Iniesta-Arandia *et al.,* 2015; Díaz-Reviriego *et al.,* 2016).

6.3.2.5 Improving financing for conservation and sustainable development

Financing is a critical determinant of the success or failure of conservation outcomes, as acknowledged in the CBD and SDG which call for increased financing and aid, and Aichi Target 3, which calls for the promotion of positive incentives for the conservation and sustainable use of biodiversity by 2020. These economic tools for biodiversity can include instruments such as biodiversity-relevant taxes, charges and fees; tradable permit schemes; and subsidies that aim to reflect the inherent values of biodiversity in their actual use, which have raised billions in recent years (OECD, 2010b; OECD, 2013). Currently, finance mobilized to promote biodiversity has been estimated at about US$ 52 billion globally (Parker *et al.,* 2012; Miller, 2014), while estimates of the financing necessary to reach international targets range from US$ 76-440 billion per year (CBD, 2012; McCarthy *et al.,* 2012). An estimated 80 percent of biodiversity conservation funding across low and middle income countries is derived from international aid (ODA), with the remaining 20 percent coming from domestic, private and other sources (Hein *et al.,* 2013; Waldron *et al.,* 2013). Other forms of financing besides ODA include direct payments to those who conserve biodiversity through various transfer mechanisms, including PES (see section on *Improving REDD+ and PES,* above), eco-compensation policies, or ecological fiscal transfers (see Supplementary Materials 6.2.4 for details on the latter two). Other financing mechanisms can include tradable permits, in which markets, auctions or other schemes allow those causing biodiversity loss or pollution to compensate their environmental impacts in other locations (see Supplementary Materials 6.2.4).

Though uncertainty exists on overall funding levels (Tittensor *et al.,* 2014), there is widespread agreement that resources are well below needs (James *et al.,* 1999; McCarthy *et al.,* 2012; Waldron *et al.,* 2013) and have failed to meet donor commitments (Miller *et al.,* 2013). Developing country capacity to finance conservation and sustainable use is increasing (Vincent *et al.,* 2014), and initiatives such as the UNDP BIOFIN project (www.biodiversityfinance.net) have assisted countries with identifying options, but ODA is likely to remain the major finance source for now. Existing flows have generally been well-targeted to countries with greater conservation need (Miller *et al.,* 2013), but there is inconclusive evidence about whether these resources have resulted in conservation success. New trust fund and collective fund approaches have been used in recent projects, such as the Amazon Fund to combat deforestation in Brazil (see Supplementary Materials 6.2.4). However, few if any peer-reviewed studies explicitly examine the impact of specific biodiversity financing projects using robust program evaluation methods. Bare *et al.* (2015) find higher rates of forest loss correlated with aid (concluding not that aid caused loss, but that aid was insufficient to halt existing drivers), while Waldron *et al.* (2017) found that conservation funding —much of it is ODA—did reduce biodiversity loss by an average of 29%. There is a paucity of impact evaluations in the conservation sector that examine socio-economic impacts of financing (Börner *et al.,* 2016; Puri *et al.,* 2016). Finally, there is a major gap in assessing the long-term impacts of conservation aid (Miller *et al.,* 2017) (see also Supplementary Materials 6.2.4). All of these gaps suggest a strong need for better systems of tracking and assessing the impacts of different types of financing; in other words, not just more financing is needed, but better understanding of the mechanisms for success.

6.3.3 Integrated Approaches for Sustainable Marine and Coastal Governance

Marine and coastal areas, covering 70% of the Earth's surface, include the High Seas or areas beyond national jurisdiction (ABNJ) which cover nearly half of the Earth's surface (Harris & Whiteway, 2009) and territorial waters from the baseline to national territorial limits. Adding river catchments affecting coastal areas means that much of the Earth's surface is directly connected to marine and coastal biodiversity and ecosystem services. Policy instruments for coastal biodiversity and ecosystem management span the scale of institutions from global and intergovernmental to local communities, and concern many different sectoral, thematic and cultural stakeholder and rights-holder groups. The United Nations Convention on the Law of the Sea (UNCLOS) includes provisions for coastal States to exercise national jurisdictions within 200 nautical miles from the baseline and to meet responsibilities for their Flag vessels on the High Seas.

Most Aichi Biodiversity Targets are relevant to marine and coastal biodiversity, but Targets 6, 7, 10, and 11 are explicit in their coverage of fisheries sustainability and ecosystem-based management (Target 6), sustainable aquaculture (Target 7), and coral reefs subject to anthropogenic pressures and impacted by climate change and ocean acidification (Target 10), and protected areas (Target 11). The ambitious target dates of 2015 (Target 10) and 2020 (Target 6, 7 and 11) have not or will not be met globally by 2020. For the SDG, Goal 14 (life below water) is most explicitly relevant to marine and coastal biodiversity, but most other Goals are also relevant.

At the frontier between land and seas, coastal areas support dense human populations, are undergoing rapid economic development and have been heavily transformed e.g., into cities, ports, tourist facilities and aquatic farms, with profound consequences for biodiversity and ecosystem services such as wildlife habitats and clean water. Downstream of terrestrial material flows, deltas and estuary systems receive nutrient, sediment, sewage, waste and pollution loads from distant regions. On land and sea margins, climate and other hazards are often more severe than inland (United Nations World Ocean Assessment, 2017). Coastal rehabilitation offers some opportunities to partially restore some ecosystem functions after their initial transformation or destruction for human use.

Climate change and pollution caused by land and sea-based carbon emissions and waste disposal are impacting the High Seas and coastal areas. Direct human exploitation of the High Seas is also increasing from fishing, shipping, oil and gas extraction, seabed mining, ocean energy production and aquaculture. Consequently, biodiversity conservation is a key issue in the High Seas (World Ocean Assessment, 2017; Ingels *et al.,* 2017). High Seas biodiversity is experiencing predominantly negative impacts, e.g., Census of Marine Life (Ausabel *et al.,* 2010), including in the abundance and diversity of fauna and in the status of sensitive and unique habitats such as seamounts (Koslow *et al.,* 2017), hydro-thermal vents (LeBris *et al.,* 2017) and deep-sea corals (Cordes *et al.,* 2017).

The use and management of coastal and marine areas are divided among many individual and corporate players whose activities impact the oceans. Unless action is based on sound shared knowledge, the players may fail to act in the interests of conservation (World Ocean Assessment, 2017), e.g., when coastal reclamation projects proceed in ignorance of the potential destruction of ecosystem services. In addition, the rights of different players may be unequal. For example, IPLCs are often long-established inhabitants and users of the coastal environment, but their access and ownership often are not secured against larger economic activities.

Following the Rio 1992 Earth Summit, conservation groups, governments and researchers increased attention to fisheries and other coastal industries impacting biodiversity and ecosystem services (Spalding *et al.,* 2013; Garcia *et al.,* 2014). Despite the raised awareness, action has been slow. For example, despite the ocean's importance in climate, oceans will be a major priority only in the 6th assessment cycle of the IPCC, due for completion in 2022. After ten years of discussion, in 2017, the UN General Assembly resolved (Resolution 72/249) to convene a conference to develop an international legally binding instrument under UNCLOS in order to address the conservation and sustainable use of marine biodiversity of ABNJ and marine genetic resources benefits sharing.

Governance of marine conservation still faces major challenges including a lack of proper international and regional legal framework for emerging challenges such as the impact of climate change on marine biodiversity.

Another major problem is non-implementation of existing legal instruments in international, regional and national levels. Cases that illustrate these problems have been exposed in the IPBES regional assessments. For instance, the regional assessment for Europe and Central Asia highlights that, although the Regional Seas Conventions are playing an important role in joint management of marine areas, the performance is uneven and application not consistent with modern conservation principles and capacity of the region (IPBES, 2018a). The regional assessment for Asia and the Pacific highlights the absence of regional seas conventions or other binding legal instruments for promoting regional joint governance of marine areas (chapter 6, pp. 520-525).

This section presents both short and long-term policy options contributing to integrated approaches to marine and coastal governance. This ranges from identifying governance gaps, including in legal frameworks, and conditions that may facilitate the implementation of available policies in response to immediate needs **(Table 6.4)**.

Table 6 4 **Options for integrated approaches for marine and coastal governance.**

Short-term options	Long-term options (in the context of transformative change)	Key obstacles, potential risks, spillover, unintended consequences, trade-offs	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Global marine and coastal					
Implementing global marine environment agreements for shipping		• Industry resistance due to competitive pressures, lack of awareness and lack of commitment • Practical weaknesses undermining the agreement effectiveness, e.g., flag state enforcement of MARPOL • More enterprises operating outside legal regimes	• International (e.g., IMO) • Regional (inter-) governmental organisations, • national, sub-national and local governments, including government linked authorities, e.g., port management • Shipping and logistics industry	International, regional, national, local	Economic, institutions
	Mainstreaming climate change adaptation and mitigation into marine and coastal governance regimes	• Lack of scientific knowledge to design practical measures • Lack of funding, industry and government support • Risk of resource declines, loss of human living space, food Lack of governance mechanisms to coordinate responses on necessary scales	• International inter-governmental agencies, • International and regional funding bodies • Regional and national sectoral agencies • Conservation-directed public-private financiers • Science and educational agencies • Donor agencies • IPLCs	International, regional, national, local	Economic, institutions, governance, technological

Short-term options	Long-term options (in the context of transformative change)	Key obstacles, potential risks, spillover, unintended consequences, trade-offs	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
	Mobilising conservation funding for the oceans	• Lack of private sector funding and very high reliance on public funds • Lack of investment assurance • Need for innovative financing mechanisms	• Maritime industries • International and national, governments	International, national	Economic, institutions, governance
International waters: High Seas (ABNJ) and regional waters					
Improving shared governance		• Maritime territory disputes • Ocean grabbing and failure to fully incorporate human dimension in conservation and resource governance • Differences in legal regimes of adjacent regions	International, regional, national and local governments	International, regional, national, local	Economic, institutions, governance, regional conflicts
Mainstreaming nature and its contributions to people		• Low national priority to biodiversity conservation • Current sectoral conservation efforts often need scaling up • Enforcement costs high, but electronic methods offer new options • Conservation and sectoral agency efforts need greater coherence	• International, regional and national governments, management agencies, NGOs, industry, IPLCs, Consumers	International, regional, national	Economic, institutions, technological, governance
	High Seas convention	• No legally binding international law for comprehensive protection of biodiversity	• International and national governments, • Non-governmental agencies, • Private sector	International, national	Economic, institutions, governance
Coastal waters					
Promote integrated management		• Long time frame and planning often stronger than implementation; • High transactions costs or fixed trade-offs can make system slow to respond to changing pressures or needs of coastal communities	• National central, sectoral agencies, NGOs, local and sub- national agencies, private sector specific to context, IPLCs	National, local	Economic, institutions, technological, governance
Mainstreaming nature conservation in sectoral management, with an emphasis on fisheries		• Widespread overfishing, pollution and habitat destruction, subsidies, IUU, market incentives • Weak progress in implementing existing fisheries governance framework • Solutions are context specific	• National governments, private sector management options, regional and international organisations, NGOs, industries and fishers organisations	International, regional, national	Economic, patterns of production, supply and consumption, governance, technological
Scaling up from sub-national project pilots		• Local conservation needs often precede national policies, but scaling up local solutions enables cooperation across local jurisdictions • Locally developed solutions may not be fully transferrable to other local situations	• National and local governments, IPLCs, Citizen groups	National, local	Economic, institutions, governance

Short-term options	Long-term options (in the context of transformative change)	Key obstacles, potential risks, spillover, unintended consequences, trade-offs	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Building ecological functionality into coastal infrastructure		• Ineffective planning and approval processes for development • Insufficient financial and human resources for monitoring	• National and local governments, private sector	National, local	Economic, institutions, governance
Engaging stakeholders to achieve common ecological and social good outcomes		• Stakeholders not working together on solutions	• International and national NGOs, private sector governments, scientists and educationists, IPLCs	International, national, local	Economic, institutions, governance, cultural

6.3.3.1 Global Marine and Coastal

Overarching global policies and processes, including and beyond climate change-related agreements have had major impacts on action to protect marine and coastal biodiversity and ecosystem services (chapter 2.1 and 3). In the present section, we focus on key global agreements that need to be integrated into policy for marine and coastal biodiversity and ecosystem services.

6.3.3.1.1 Implementing global marine environment agreements for shipping

History shows that global agreements regarding shipping are challenging to negotiate, and, once agreed and ratified, challenging to implement, and in motivating government, industry and community stakeholders to act. The existing conventions and protocols on vessel-sourced pollution, including exotic and potentially invasive species from ships' hull fouling and ballast water, are important examples as shipping grows (World Ocean Assessment 2017, chapter 17).

Several international maritime agreements on the environment pre-dated UNCLOS, notably the International Maritime Organization (IMO) International Convention for the Prevention of Pollution from Ships, 1973 – MARPOL (Karim, 2015). UNCLOS was critical, however, as it introduced the regulatory framework of duties and jurisdiction of states addressing the main sources of ocean pollution, the success of which heavily depends on detailed regulations and their enforcement by international, regional and national institutions. Despite wide convergence of shipping issues and participation of most of the countries as well as the considerable success of IMO Conventions, worldwide uniform enforcement, monitoring and control still need development (Karim, 2015). Enforcement, monitoring and control relied greatly on flag state enforcement (Mattson, 2006) but in addition, port-state enforcement is being applied in some maritime agreements, such as the Food and Agriculture Organization Agreement on Port State Measures to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing (2009). This combined with new satellite and information technologies are being applied in efforts to track compliance, but enforcement is still weak (Petrossian, 2015). Enforcement and implementation are lacking both within and beyond national jurisdiction (Karim, 2015, 2018), but regional cooperative arrangements may improve regulatory capacity and should be further strengthened. In addition, a coordinated and widespread initiative for capacity building to strengthen understanding of and capacity for flag state responsibility in the global regulatory apparatus is needed to combat pollution in the areas beyond national jurisdiction (World Ocean Assessment, 2017).

6.3.3.1.2 Mainstreaming climate change adaptation and mitigation into marine and coastal governance regimes

Coordinated measures are needed to combat climate-related stressors on marine biodiversity, e.g., ocean acidification, ocean warming and deoxygenation (Bijma *et al.,* 2013; Pörtner, 2014; Levin *et al.,* 2018), as these stressors have sectoral effects, such as on stable fisheries agreements (Brandt & Kronbak, 2010; Galaz *et al.,* 2012). In fact, the Paris Agreement is now the first climate agreement to explicitly consider the ocean. International and regional legal instruments and mechanisms for climate change, oceans, fisheries and the environment are relevant for these challenges, but they remain inadequate (Galland *et al.,* 2012; Herr *et al.,* 2014; IPCC, 2017). At the least, sectoral and general ocean governance will have to mainstream major climate issues in governance regimes at international, regional and national levels. This mainstreaming will help sectoral management adapt and mitigate emissions. If linked to climate actions, this may also help reduce some of the knowledge gaps on climate and the ocean, and gaps between scientific and government attention to climate change (Magnan *et al.,* 2016; Gallo *et al.,* 2017). Achieving policy coherence over such complex issues also requires significant new knowledge on the oceans and climate which can feed back into climate science. In the case of proposed climate solutions such as geoengineering to capture carbon from the atmosphere, the IPCC warns that the impacts on marine ecosystems "remain unresolved and are not, therefore, ready for near-term application" (http://www.ipcc.ch/ipccreports/tar/wg3/index.php?idp=25).

Many impacts of global changes are highly unbalanced, because telecouplings affect people who have not caused the problems. Sea level rise is eroding the living space of many marginal coastal people in developing countries, e.g., on low-lying Pacific islands and coastal mangroves in Asia. Funds set up to address these transfer issues, e.g., the Green Climate Fund and other multilateral instruments will not have their intended effects unless greater priority is given to developing countries (Friends of the Earth and Institute for Policy Studies, 2017), and these funds need to specialize and cooperate effectively to provide coherent support (Amerasinghe *et al.,* 2017).

6.3.3.1.3 Mobilising conservation funding for the oceans

According to some estimates, the oceans provide trillions of USD annually in goods and services to society (Costanza *et al.,* 1997). Policies and incentives towards the sustainable use of the oceans – from controlling overfishing and pollution to promoting new technologies for energy and carbon sequestration to incentives for sustainable tourism – have economic and social impact across sectors of society and regions, benefiting private and public economies, and local communities. However, innovative solutions are needed for improving financing for conservation action for the ocean. Some estimates suggest that that market-based mechanisms could, for example, deliver up to 50% of the finance for coral reefs (Parker *et al.,* 2012), including for instance cap-and-trade programs such as the Ocean Appreciation Program (Ocean Recovery Alliance, 2016), green bonds (Thiele, 2015a), and blue carbon sequestration to benefit biodiversity (Maldonado & Barrera, 2014; Murray *et al.,* 2011; Thiele & Gerber, 2017). On the High Seas, the financial mechanisms to support conservation are not well established and new institutional financial structures, including financial solutions that allow for private funds to be invested in conservation, such as from international markets, are increasingly recognized as essential (Madsbjerg, 2016).

The majority of current biodiversity funding is from public finance (e.g., GEF) (Huwyler *et al.*, 2014) and is affected by the short-term time horizons of political agendas and public opinions. Following models used in climate (Buchner *et al.,* 2015) and development finance (Gutmann & Davidson, 2007), growing attention is given to the potential use of market-based mechanisms used in terrestrial systems for the High Seas, such as payments for ecosystem services and biodiversity offsets (Gjertsen *et al.,* 2014).

Clean, renewable ocean-derived energy has the potential to reduce carbon emissions and meet 10 percent of EU demand by 2050 (Ocean Energy Europe, 2015). Technologies of this magnitude, however, are impeded by high initial investments and risks. These barriers may be overcome through public-private collaboration and require careful planning and environmental impact assessment (Economist Intelligence Unit 2015). There is potential for increased research and infrastructure support for wave and tidal energy technology, which have been slow in terms of technological advancements (REN21, 2018; Bruckner *et al.,* 2014).

A portion of the profits from ocean-based goods and services could be directed into conservation research, monitoring, and enforcement. For example, ocean tourism, managed with respect for, with and by local communities, can yield successful results if earning from tourism are funneled into supporting sustainable management (Cisneros-Montemayor *et al.,* 2013; Hess, 2015); and appropriate incentives in fishing could help change current practices such as derelict gear that threaten habitats and natural capital stocks (Grafton *et al.,* 2006; Grafton *et al.,* 2008).

Global cooperation is needed to develop innovative mechanisms to conserve the ocean, just as global collaboration is needed to address air quality and atmospheric emissions. Ocean conservation projects may be funded by a proposed Ocean Bank for Sustainability and Development and trust funds. The Ocean Bank concept has been supported by several NGOs that argue current development banks and structures are not sufficient for the largest ecosystem (WWF, 2015). Proponents envision that this new institution arrangement could be funded by states and private investors, providing knowledge, project development, training, and financing (Cicin *et al.,* 2016). Trust funds can offer long-term financial assistance and have already been applied to marine conservation management (MAR Fund, 2014; MRAG, 2016), e.g., a fund for a protected area in Kiribati compensates the government for license profits forgone (MRAG, 2016).

In the last 20 years, conservation organisations – international, national and local – e.g., IUCN, WWF, CI, TNC, WCS and their local chapters – have developed major coastal conservation programs, supported by funding from (mainly) US based philanthropic foundations (Packard, Walton, Pew, etc.) and often giving particular attention to charismatic ecosystems, e.g., coral reefs, and mega-fauna, e.g., whale shark, cetaceans and other marine mammals, and penguins. However, as the foundations turn more to Blue Economy issues such as fishing and food security, their future efforts may not be so focused on biodiversity conservation, calling attention to the importance of diversifying funding mechanisms supporting marine and ocean conservation and sustainable use.

6.3.3.2 International waters: High Seas (ABNJ) and regional waters

Significant areas of the ocean are outside settled national jurisdictions, although certain activities may be under the controls of regional bodies or of global agreements. Some disputes over precise jurisdictions remain. A few countries, including the USA, have not signed the United Nations Convention on the Law of the Sea (UNCLOS), but largely abide by its provisions. The High Seas sustain global-scale ecosystem functions and provide essential benefits to humans (Rogers *et al.,* 2014) but are subject to three increasing trends (World Ocean Assessment, 2017). First, human needs are increasingly met from the ocean, some directly, e.g., food from fisheries, aquaculture and ranching (Ferreria *et al.,* 2017; APEC, 2016), and some indirectly, e.g., greater shipping of commodities in an increasingly globalized world (Simcock & Tamara, 2017; Simcock, 2017). Second, direct drivers affecting the High Seas are expected to increase, including fishing, aquaculture, mining, energy and defence activities, sound pollution from transportation, and chemical and biological pollution from increased use of the sea and coastal living. Third, as efforts to increase the sustainability of ocean uses within national jurisdiction increase (FAO, 2016; CBD, 2017), some of the effort is moving offshore (Merrie *et al.,* 2014; Gjerde *et al.,* 2013). These three trends have major impacts on nature and its contributions to people, including the challenge of managing rapidly emerging industries such as mining, undersea communications and energy. Improving shared governance, mainstreaming nature, and a new High Seas convention are proposed as options.

6.3.3.2.1 Improving shared governance

Supporting and expanding existing conservation cooperation mechanisms represent a promising short-term option for protecting High Seas biodiversity. Some of these institutions are expanding their initiatives into areas beyond national jurisdiction, e.g., through fisheries observer programs, anti-IUU (illegal, unreported and unregulated) fishing measures. Regional organisations, particularly, the Regional Seas Programmes, Regional Fisheries Management Bodies and their conventions, and GEF Large Marine Ecosystems (LME) programmes can also play an important role in combating land-based marine pollution.

A common first step in establishing international coastal cooperation is a transboundary programme of technical cooperation, such as the Regional Seas Programmes and Conventions and the GEF initiated LME projects. Many of these programmes have helped create effective environment agreements among countries.

Territorial disputes may impede conservation, to the extent that in contentious areas, multilateral cooperation has been limited to technical cooperation among a subset of countries rather than active management (Williams, 2013). Where maritime territory disputes remain, countries are urged to settle these through the UNCLOS legal routes. UNCLOS offers four options for dispute settlement and by finding the means that best suits, states have settled many disputes. However, instances where some of the large powers have opted not to resort to UNCLOS dispute settlement system may jeopardize the effectiveness of the forum (Klein, 2014; Gates, 2017).

"Ocean grabbing" is a term used to describe an emerging concern over the dispossession or appropriation of ocean space or resources from prior users, rights holders or inhabitants resulting from governance processes with power asymmetries among participants. More broadly, the issue of accumulation by dispossession is both an issue that can impede conservation and be used by conservation interests to obtain a foothold over community lands (Harvey, 2003; Hall, 2013; Benjaminsen & Bryceson, 2012). If the needs of local communities and ecosystems are not fully taken into account, allocation of access rights to ocean space or resources may undermine human security and impair biodiversity components. Conservation allocations such as marine protected areas, and rights-based approaches such as individual fisheries quotas may be conducted in ways that do not undermine human security and ecological functions (Bennett *et al.,* 2015).

Thinning and disappearing sea ice, melting permafrost, and circumpolar climate change, however locally and regionally varied, are commonly identified as playing their part in rapidly unsettling the geographies of Arctic governance (Overland & Wang, 2013; Smith & Stephenson, 2013; Hussey *et al.,* 2016; Stephenson, 2018). Strategies are being sought that will promote renewed international cooperation and reduce the risks of discord in the Arctic, as the region undergoes new jurisdictional conflicts and increasingly severe clashes over the extraction of natural resources in a region that is critical to the prevision of globally important NCPs (Berkman & Young, 2009; Young, 2010; Keil, 2015; Hussey *et al.,* 2016; Harris *et al.,* 2018).

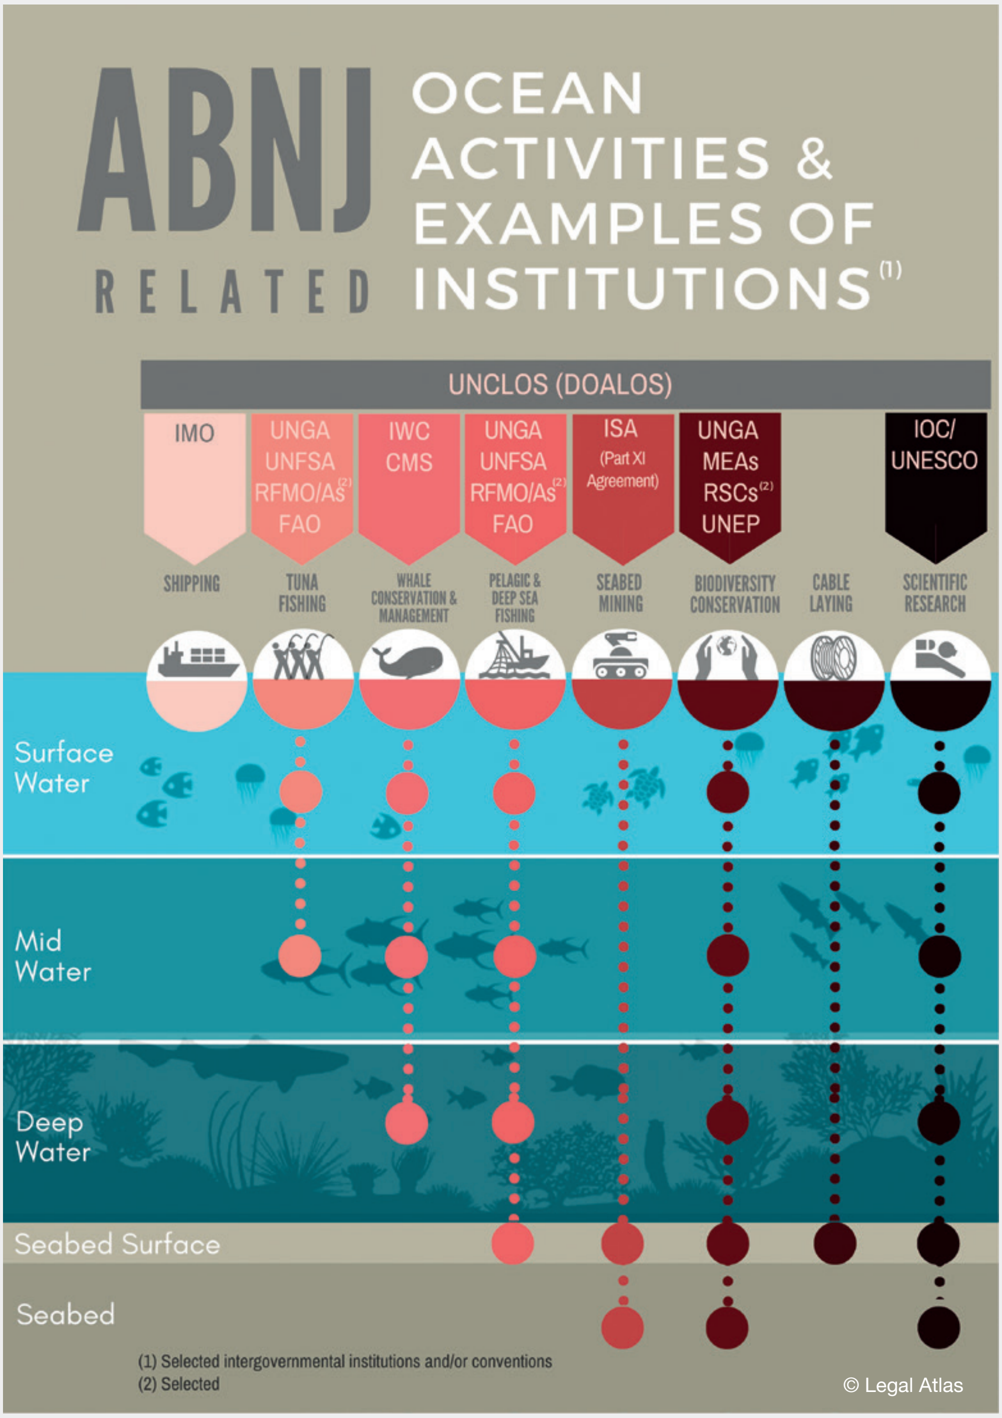

Figure 6 3 **Multiple ocean uses and examples of institutions related to areas beyond national jurisdiction illustrating the different ocean depths relevant to the activities and institutions.**

Source: UNEP-WCMC (2017).

Several organizations have advocated for the negotiation of a harder law regime for the Arctic (Kankaanpää & Young, 2012), including firmer institutional, financial and regulatory foundations for the Arctic Council (Berkman & Young, 2006) and improved transboundary conservation planning (Greenpeace, 2014; Hussey *et al.,* 2016; Edwards & Evans, 2017; Harris *et al.,* 2018).

6.3.3.2.2 Mainstreaming nature and its contributions to people

Recognising the rising pressures on biodiversity on the High Seas, most sectoral regulatory agencies are recognizing the need to mainstream biodiversity conservation into their approaches to policy and management (CBD, 2016). Responding to growing public pressure from NGOs and international agencies, measures are being introduced. For instance, Regional Fisheries Management Organisations (RFMOs) are implementing UNGA Resolution 61/105 to protect deep sea Vulnerable Marine Ecosystems (VMEs) from bottom trawling (Rice *et al.,* 2017). Similarly, sectoral agencies such as the International Seabed Authority for deep-sea mining (Anton, 2011) and International Maritime Organisation for shipping are adopting, or urged to, additional policies and measures to manage and mitigate the pressures of these sectors on High Seas biodiversity and their habitats.

The effectiveness of conservation policies for the High Seas depend crucially on how well they are implemented, a challenge that sectoral regulatory agencies have been grappling with for decades. In some areas, there is a need for substantive scaling up resources and prioritizing areas of rising pressure, e.g., for tuna fisheries (Juan-Jorda *et al.,* 2017). A major obstacle is the lack of priority that countries give to international arrangements for nature conservation. The latter highlight the role of regional management bodies and their secretariats in mobilizing action, and that of NGOs that advocate action through campaigns engaging public attention and presenting submissions to management bodies.

The experience of RFMOs in protecting VMEs from deep sea fishing shows that a strong science foundation is crucial as the knowledge basis (MacDonald *et al.,* 2016), in addition to guidance on suitable conservation management measures (FAO, 2009). As little of the seabed is mapped, however, the knowledge base is generally poor. Protection is still feasible using responsive mechanisms based on existing knowledge, e.g., real-time move-on (cease-fishing) rules triggered when the presence of a VME is identified through bycatch indicator taxa; and great progress on identifying VMEs and Ecologically and Biologically Significant Marine Areas, even with incomplete information (Dunn *et al.,* 2014).

For RFMOs and other sectoral agencies, member States need to provide costly surveillance and enforcement (Rice *et al.,* 2014). These functions present a greater challenge on the High Seas than within national jurisdictions, but additional policy interventions have enhanced the effectiveness of existing policies, e.g., the FAO Port State Measures Agreement (2009, in force 2016) increased the effectiveness of other measures to deter IUU fishing (FAO, 2017). Sectoral management agencies, including fisheries, and NGOs such as Global Fishing Watch, are now testing new technologies such as satellite monitoring of electronic fisheries operations, onboard CCTV monitoring of catch and bycatch, and real-time data entry (Hosken *et al.,* 2016). These technologies can lead to better monitoring, control and surveillance.

Greater efforts are needed to achieve coherence between the efforts of sectoral management agencies and the efforts of biodiversity conservation agencies, including those led by intergovernmental organizations such as the CBD, e.g., program for identifying Ecologically or Biologically Significant Areas (EBSAs – Johnson *et al.,* 2018), and by NGOs, e.g., Birdlife International. In fisheries, poor coherence leads to low returns on conservation and management investments (Garcia *et al.,* 2014a). The obstacles to improving coherence are high because it requires governance processes with convening power to bring the agencies together, the duty to cooperate both in selecting policies and measures that work synergistically and implementation strategies that encourage cooperation (Garcia at al., 2014b).

6.3.3.2.3 Pathways to protect nature in the High Seas

The need for coherence poses the greatest challenge, and greatest opportunity, for changing the trends of loss in High Seas biodiversity. The limitations of UNCLOS to deal effectively with nature conservation in the High Seas biodiversity was recognized over a decade ago. Open Ended Working Groups of the UNGA (http://www.un.org/depts/los/biodiversityworkinggroup/biodiversityworkinggroup.htm) prioritized three themes: the ability to apply spatial management tools, including High Seas Marine Protected Areas (MPA) binding on all marine industry sectors; marine spatial planning across sectoral agencies; access and benefits sharing to marine genetic resources; environment impact assessment, technology transfer and capacity building.

UNGA has initiated in 2017 an intergovernmental conference on an international legally binding instrument under UNCLOS on the conservation and sustainable use of marine biological diversity of areas beyond national jurisdiction (General Assembly Resolution 72/249); with expected conclusion in 2020. These negotiations will be a major factor in the future trajectories of High Seas biodiversity. An eventual future instrument is likely to include provisions for area-based management including MPA, environmental impact assessment and marine genetic resources. National government are encouraged to support the timely agreement of an effective instrument for marine protection and then implement the provisions with regard to key sectors, e.g., fishing, seabed mining, coastal oil and gas, geoengineering and waste disposal.

6.3.3.3 Coastal Waters

National governments play a major role in determining the balance of coastal protection and resource use, and global codes and conventions can help promote national action, e.g., SDG 14 (life below water). Governments face the challenges of harmonising and coordinating responsible agencies and interests, setting national policies and priorities, coordinating and integrating planning, resourcing, implementing, monitoring and reporting. Locally led initiatives can also feed up into national policies (see 6.3.3.3.3).

6.3.3.3.1 Promoting integrated management

Since the 1980s integrated coastal environment management concepts have been a focus of academic attention (Merrie & Olsson, 2014). Conservation, international and national organisations also have promoted, developed and piloted several related forms of integrated marine and coastal management, especially Integrated Coastal Management (ICM) and Sustainable Development in Coastal Areas (ICM/SDCA – http://www.pemsea.org/our-work/integrated-coastal-management/SDCA-framework), MPA, Marine Spatial Planning (MSP) (Ehler & Douvere, 2009) and Ecosystem Based Management (EBM) (Agardy *et al.,* 2011). MSP and MPA illustrate the challenges.

MPA have been applied most commonly to fisheries and special area conservation. Their effectiveness depends on the economic conditions, governance and institutional contexts in which in which they are applied (Agardy *et al.,* 2011; Ban *et al.,* 2013; IPBES, 2018c), their location (Mouillot *et al.,* 2015), and local livelihood activities that are displaced by the MPA must be addressed (Cudney-Bueno *et al.,* 2009; Bennett & Dearden, 2014; IPBES, 2018d).

Conversely, when MPA management incorporates biophysical, economic, and social characteristics of the system, more sustainable fishing practices may result (Cinti *et al.,* 2010; Sciberras *et al.,* 2015; Gill *et al.,* 2017).

MPA and systems of interconnected MPA offer conservation management options for both the short and long term, for governments, private, NGO, and IPLC actors. The social and economic benefits of MPA can improve community well-being via increased income from fisheries or tourism (McCook *et al.,* 2010), and IPLCs can engage in stakeholder processes so that MPA benefit both people and nature (Bennett & Deardan, 2014). The private sector can contribute innovative financing for implementing and enforcing MPA (Theile & Gerber, 2017). Rights-based approaches to MPA management and ocean governance offer a promising option to strengthen MPA and MPA Networks implementation (Bender, 2018). NGOs have an important role to play in implementing MPA, through assisting community engagement and capacity building, monitoring and evaluation, and developing and implementing economic incentives to support MPA (Mascia *et al.,* 2009).

Marine spatial planning (MSP) is a comprehensive "public process of analyzing and allocating the spatial and temporal distribution of human activities in marine areas to achieve ecological, economic, and social objective *that are usually specified through a political process."* (IOC-UNESCO Marine Spatial Planning Programme – http://msp.ioc-unesco.org/). It evolved together with MPA developments (Katsanevakis *et al.,* 2011), bringing together multiple users of the ocean – energy, industry, government, conservation and recreation. Not an end in itself, intent of MSP is a coordinated and sustainable approach to ocean use. Policy-relevant guidebooks have been developed to support implementation (e.g., Ehler & Douve, 2009). Despite good pilot cases and some success, a 2012 review concluded that: "Comprehensive MSP initiatives are relatively new and thus largely untested. In those that are underway, there appears to be greater emphasis on planning than on post-plan implementation" (Secretariat for the CBD and GEF, 2012, p.32). Furthermore, the requirements of cross-sectoral decision-making can be seen by line ministries as onerous and undesirable (Secretariat for the CBD and GEF 2012), although this is clearly very important in implementing the mainstreaming requirements of the CBD. A further challenge is that the adaptable nature of MSP must continually maintain a balance of ecosystem conservation and economic and social aims (Merrie & Olsson, 2014), making frequent updates and adaptive responses necessary. National capacity to implement integrated environmental stewardship can be affected also by the relative powers of the ministries. In some governments, environment ministries are newer and weaker compared to economic and central ministries (Jordan *et al.,* 2010).

Overall, the obstacles to implementation, longer time frame for success, complexity of the integrated solutions, and need to be responsive to changing externalities (e.g., climate change, new trade agreements, changing markets for traditional products, etc.) all mandate that governance arrangements focus also on shorter term responsive action, including sectoral in cases, to address the most immediate problems in a step by step approach. Nevertheless, sectoral or local actions need to be nested with higher level institutions adjudicating on cross-sectoral trade-offs resulting from specific actions, such as those competing for coastal space: ports, urban development, fisheries, tourism, and conservation.

Integrated management at the national and local levels: National governments, pivotal to integrating management across scales and to negotiate international and regional agreements. Typically, an international agreement is the catalyst for national action, however avoiding piecemeal solutions is difficult since local and national levels actors are continuously responding to accelerate social and environmental changes. On the other hand, localized solutions can be effective. For instance, while a global instrument against plastic pollution will take time, national and sub-national actions are contributing to address the problem (Niaounakis 2017). National and state governments, for instance, can impose restrictions on the sale and use of single-use plastic bags, for instance as did Chile in 2017 in restricting such items particularly in coastal villages and towns.

Decentralizing policies to sub-national and local governance have a direct impact on the type of coastal and marine management. In the last three decades, coastal and marine management has been affected by the opportunities and challenges caused by national re-organisations associated with the devolution and decentralisation of government powers to state, province or local government and community levels, requiring rapid capacity building at sub-national levels. In Southeast Asia (e.g., Indonesia, Philippines and Vietnam) devolution models were embraced with varying results. Indonesia has received major World Bank development and conservation support for community and local government-based empowerment, and the local outcomes covered the spectrum from responsible leadership, to elite capture, patronage networks, and outright corruption (Warren & Visser, 2016). Another example of diverse outcomes of local level management is the coastal cities in the Great Buenos Aires conurbation (Argentina), comprising ten different jurisdictions at national, provincial and municipal government level. Responding to local politics and globalization pressures on competitive industries, decades of decentralization or federation efforts were resolved essentially in favour of decentralisation rather than metropolitan integration (Dadon & Oldani, 2017).

Successful short and medium-term sub-national interventions can include small scale actions and projects at sectoral or cross-sectoral level, as for this scale, sectoral boundaries may not be so rigidly delineated. Technical projects, research institutes (as entry points for diagnosis, finding solutions, monitoring status) and community, including youth, engagement, are critical elements to the success of grassroots conservation.

Indigenous Peoples and Local Communities are central to sub-national marine conservation action but vary significantly in terms of their capacities and needs to manage marine resources under different types of pressures. Across the world, the position and contribution of IPLCs to coastal management vary significantly from areas where communities retain full control to various types of mixed arrangements, to complete deprivation of rights. Evidence demonstrates that local customary institutions can be more effective than formal external ones in promoting management. In Indonesia, continuous traditional marine management such as *sasi laut* and *pangalima laut* were more potent and likely to be obeyed than more modern proclamations, e.g., of Marine Protected Areas (Harkes & Novaczek, 2002; Wiadnya *et al.,* 2011). In Sumatra with well-conceived external support, even cases of corrupt devolved authority could be turned around into local community advantage (Warren & Visser, 2016).

6.3.3.3.2 Mainstreaming nature conservation in sectoral management, with an emphasis on fisheries

National resource managers of coastal waters, private sector enterprises, citizens and consumers can all play a role to help prevent environmental damage, including by protecting vulnerable areas, changing damaging manufacturing practices, sensitive land development, waste disposal and consumption patterns. Collectively, these mainstreaming approaches are now being referred to as ecosystem-based approaches to management within specific sectors. Sectoral activities and policy often determine the conservation approaches but focus on components of nature most closely linked to their sectoral activities. For example, fisheries experts have been early to diagnose environmental problems such as fish stock overexploitation and bycatch, but less likely to focus on a seabird colony finding insufficient food because of a fishery harvest. Effective governance is needed to ensure sectors do not prioritize resource uses to a level that risks unsustainable practices.

In addition to risk of overharvesting, the IPBES regional assessments for Africa, the Americas, Asia and Pacific, Europe and Central Asia found that fisheries conservation is threatened also by other external threats, including many types of pollution, habitat destruction for industries and human living space, invasive alien species from sources including ballast water introductions, nutrient driven hypoxia, jelly-fish blooms, and climate change. These problems call for the joint effort of governance institutions from local, to national, and regional, and even global.

Managing the impacts of fishing and fish supply chains to conserve the target stocks and the environment has become a recognized environment priority, e.g., SDG target 14.4 and Aichi target 6. One-third of marine fish stocks (including invertebrates) are fished at biologically unsustainable levels, 60% at sustainable levels, and 7% underfished (FAO, 2018a). However, many marine fish stocks are of unknown status, suggesting that estimates about sustainable fisheries management may be over-optimistic (FAO, 2018a). Positively, there is evidence that stock rebuilding is occurring in countries including USA, Australia, Namibia, Canada, and the European Union (FAO, 2018a). However, evidence on ending overfishing and rebuilding depleted stocks suggests that the successful recovery of depleted marine resources depends possibly more on management of infrastructure and socio-economic contexts than on having accurate stock assessments alone, especially if management measures that are suited to data-poor fish stocks are used (e.g. IPBES, 2018c; Brodziak *et al.,* 2008; Rosenberg *et al.,* 2006; Caddy & Agnew, 2004; Garcia *et al.,* 2018).

Despite evidence for the need to address overexploitation from fishing, many countries and RFMOs have not fully implemented the extensive international legal framework, including both hard and soft law instrument, referred to as the Code of Conduct for Responsible Fisheries and its instruments (FAO, 2012). The World Ocean Assessment (United Nations, 2017) proposed the following options: ending overfishing and rebuilding depleted stocks; eliminating IUU fishing; reducing the broader ecosystem impacts of fishing including habitat modification and effects on the food web; reducing the adverse impacts of pollution; and reducing the adverse impacts of perverse subsidies.

A major challenge is that the options are highly context specific and need to be purpose built, albeit lessons can be learned from practice elsewhere and locally specific solutions involve opportunities for co-management. Developed countries may use complex, data rich ecological-economic models (Nielsen *et al.,* 2018), but the models, management institutions and methods, e.g., catch shares, individual transferable quotas (ITQs), may not suit developing country and small-scale fisheries. Specific cultural and ecological contexts are important for successful community-based fisheries management, making any model hard to upscale (Poepoe *et al.,* 2007), although local leaders, social capital and incentives were found to be important (Gutiérrez *et al.,* 2011).

Communities making a living from small-scale fishing and coastal resources have often been ignored in national and international policy, despite their strong dependency on the resources (García-Quijano *et al.,* 2015). Furthermore, assessments, including the present one, generally neglect to consider women's role in this sector and thereby ignore major unrecorded fish catches (Gopal *et al.,* 2017). As well as women, policies need to consider the rights and concerns of Indigenous Peoples with respect to livelihoods, equity and rights, participating and contributing knowledge to fisheries and coastal ecosystem management (Capistrano & Charles, 2012; Fisher *et al.,* 2015). The 2015 Voluntary Guidelines for Securing Sustainable Small-Scale Fisheries in the Context of Food Security and Poverty Eradication (SSF-VG) were developed to overcome the neglect of local communities, indigenous and non-indigenous. Countries are encouraged to implement the SSF-VG, which incorporates comprehensive environmental as well as human rights and equity principles.

"Balanced harvest" (Garcia *et al.,* 2016) has been debated as a possible approach to increase food from the sea while maintaining sustainable fisheries but evidence on its effectiveness is lacking as it has not yet been implemented.

To address sustainability through eliminating IUU fishing, countries and Regional Fishery Bodies should not only exercise effective fisheries management, but also implement strong surveillance capacities, e.g., Petrossian, 2015, (see 6.3.3.2.1 and 6.3.3.1.1) and adequately invest in research and technical capacity, for instance improving recognition of illegal landing species and sizes (e.g., Romeo *et al.,* 2014).

Customized options to reduce and eliminate bycatch and discards are essential to minimize ecosystem impacts of fishing (Hall *et al.,* 2017; Gladics *et al.,* 2017; Gilman *et al.,* 2016, Little *et al.,* 2015; Broadhurst *et al.,* 2012). National measures to reduce the direct impacts of fishing on marine mammals, sea turtles and seabirds have proven successful (Grafton *et al.,* 2010). In fisheries for migratory species and in remote ocean areas like those in the Southern Ocean, international inter-organizational collaboration is needed (Osterblom & Bodin, 2012). In addition to managing bycatch and discards, reducing the broader ecosystem impacts of fishing depends on establishing new and implementing current MPA, and restoring critically endangered ecosystems (e.g., Kennelly & Broadhurst, 2002; Fourzai *et al.,* 2012). Adoption of the ecosystem approach to fisheries across countries has, according to FAO, been slow but has consistently moved forward (FAO, 2018b).

Fishery subsidy reforms, which includes elimination of harmful subsidies, decoupling subsidies from fishing effort, re-orienting subsidies to management and technological improvements, conditioning subsidies on fishery performance, and substitution of ongoing subsides for buyback schemes (Cisneros-Montemayor, 2016; Tipping, 2016) are innovative attempts to redress current failures in the interest of resource protection and sustainability.

Seafood certification and ecolabelling are economic instruments designed to change consumer seafood demand for well-defined target species or fisheries whose sustainability is under threat, direct them to better environmental choices, create market access, and provide incentives to improve fishing practices through price premiums to producers (FAO 2018b). The uptake of these schemes has been much greater in developed countries and is considered to have had the most important non-State positive impact on fisheries sustainability, but more efforts are needed to increase its uptake and the lower barriers to entry for developing country and small-scale fisheries (Gutierriz *et al.,* 2016; FAO, 2018b). In view of the diversity of ecolabelling and certification schemes have developed, for which FAO has established a Global Benchmark Tool. To date, only three fisheries and one aquaculture scheme have been benchmarked. Several schemes are now addressing social standards but as yet these lack agreed performance norms (FAO, 2018b). As precursors to certification, fisheries improvement programs (FIPs) are important stepping stones towards sustainability (https://fisheryprogress.org/).

Certification and ecolabelling have had a major positive impact on improving fisheries sustainability and, for developed counties, may be the most important recent non-government fisheries management initiative. Evidence shows that support of governments and other fisheries actors are essential for fisheries certification (Gutierrez *et al.,* 2016). Controversy over certificate standards and questions over accountability for the certification machinery and decisions have arisen (Miller & Bush, 2015; Gulbrandson & Auld, 2016). In addition, certification has had only modest success so far in including developing countries and small-scale fishers and producers. A further challenge is that only some consumers are yet willing to pay more for certified seafood (FAO, 2018b).

6.3.3.3.3 Scaling up from sub-national project pilots

National agencies, including government science and management agencies, play key roles identifying, diagnosing, researching and developing technical projects and pilots on marine biodiversity conservation, often following specific sub-national cases, such as Australian efforts to sustainably manage competing uses of the Great Barrier Reef Marine Park (Merrie & Olsson (2014).

Scaling up is the challenge for sub-national initiatives. In Asia, the PEMSEA partnership has demonstrated the feasibility of building on small scale local success. For example, in Batangas, Philippines, efforts spread from five local authorities to 34, covering the watershed and coastal areas of the whole province (http://www.pemsea.org/our-work/integrated-coastal-management/ICM-sites). By 2021, ICM is expected to reach 25% of the East Asia region's coastline using the PEMSEA model that has performed well in East Asia, as national governments collaborate towards a regional strategy. The work starts at the local government level, rather than relying on national policy to initiate action. Like other integrated approached, ICM relies on networks of experts reaching out to interested local actors, having also attracted attention from international donors.

Successful examples of local governance, albeit with external support in most cases, are described in the IPBES regional assessments. For instance, since 2005 in the Pacific region, locally managed marine areas have grown in number; in Madagascar, the NGO Blue Ventures is piloting payment schemes for blue carbon; and in West Africa, mangrove conservation has progressed in a six-country development project with local partners.

6.3.3.3.4 Building ecological functionality into coastal infrastructure

Given the inevitability of future coastal infrastructure development, it is vital that decision makers consider the ecological functions of coastal ecosystems from the start (Daffron *et al.,* 2015). Altered and damaged ecosystems are difficult to restore or rehabilitate, or not politically or economically feasible. Maintaining and managing natural system by removing stressors such as pollutants may be a fraction of the costs of restoration (Elliot *et al.*, 2007). In some cases, however, created ecosystems may even be culturally preferred. With the rapid increase in created coastlines, especially around urban areas, ecosystem rehabilitation, increasing attention has been paid to remediation and multi-purposing coastal structures such as breakwaters and marinas.

6.3.3.3.5 Engaging NGOs, industry and scientists as stakeholders to achieve common ecological and social good outcomes

Across countries, interpretations and awareness of the importance of conserving nature and its contributions to people in the oceans are diverse and dynamic, although a growing degree of convergence is emerging as a result of local social movements, global environment conventions and agreements, scientific efforts, and environmental advocacy. New national and local environmental NGO are emerging, creating greater and more distributed demands for conservation action. For instance, large international NGO have set up national branches and joint ventures in many countries, bringing their own concepts and values and adapting them to local circumstances and channels of influence. Although the translations do not always work, with time and experience, the short-term actions can mature to more appropriate forms for local ecosystems and species, values and knowledge, e.g., national versions of seafood consumption guides.

Powerful industry players may obstruct and even capture the political processes, e.g., port infrastructure, shipping, industrial fishing, tourism and real estate (Jenkins & Schröder, 2013; Bavinck *et al.*, 2017), but industry actors are also highly relevant to finding solutions. Options to involve private interests include corporate social responsibility, market-based instruments such as certification (e.g., seafood certification, 6.3.3.3.2) and best practice in fisheries and aquaculture production methods (Jenkins & Schröder, 2013). In the case of coastal hypoxia caused by nutrient loading, more attention is needed to engage sectors responsible for the largest point-source nutrient emissions (farmers, intensive livestock producers, agricultural chemical and fertilizers companies) in policy decision-making, remedial action, educational programmes and training sessions (STAP, 2011).

Marine assessment processes provide opportunities for management agencies, research institutes, NGO and other citizen groups to assess and report the status of nature and its contributions to people, to identify issues and suggest solutions. International collaboration on assessments and standards can enable national status reports to be shared and information to be aggregated and compared regionally and globally. In addition to international government organization assessments, such as the World Ocean Assessment, NGO and privately funded systems can contribute to collaborative efforts such as the Ocean Health Index (http://www.oceanhealthindex.org/).

6.3.4 Integrated Approaches for Sustainable Freshwater

Freshwater ecosystems include rivers, lakes, reservoirs, wetlands and groundwater systems. The options for decision makers discussed under this section are based on SDG6 (clean water and sanitation) and several Aichi Biodiversity Targets (ABTs). Population growth, climate change, increasing demand for water, institutional policies, and land-use change – all interact to determine available water supply and use (Liu *et al.*, 2013). Short and long-term options to manage water need integrated and adaptive governance that reduce pressures on water, encourage nature-based solutions and green infrastructure, and promote integrated water resource management as well as considerations of water-energy-food nexus (WWAP/UN-Water, 2018). Adaptive measures include rainwater harvesting, improved pasture management, water reuse, desalinations and more efficient management of soil and irrigation water, among others (Jiménez *et al.,* 2014). Inclusive and informed approaches to water governance open up opportunities for stakeholders with diverse interests to be involved in making decisions that are integrated, adaptive, resilient, innovative and responsive (WWAP, 2018; Ison & Wallis, 2017; Razzaque, 2009; Pahl-Wostl, 2007). Transformational change requires a move away from the business as usual approach and puts emphasis on the recognition and integration of multiple values, including intrinsic and relational values, in water management (WWAP/UN-Water, 2018; Bartel *et al.,* 2018).

The complexity of water resources is reflected in its status as an economic good as well as a public good (CESCR, 2003; Griffin *et al.,* 2013; Whittington *et al.,* 2013). It is well established that challenges to water management are aggravated as there are ambiguities in relation to the status and scope of legal rights governing access to water (McCaffrey, 2016; Murthy, 2013). It is critical to understand the combination of options and instruments that can be designed to meet policy objectives and allocations arrangements (WWAP, 2015; OECD, 2015). In the short-term, a clear legal status needs to be in place for all types of water, such as surface water, groundwater and wastewater along with a clear indication of the ownership and user rights and polluter duties. Such a legal regime will enable the responsible authority/ies to determine the level of access to be given to various users, monitor the losses in water distribution, impose sanctions such as fines or penalties, and determine the response measures in cases of exceptional circumstance, such as drought and severe pollution (Ring *et al.,* 2018; Acosta *et al.,* 2018; Stringer *et al.,* 2018; Scarano *et al.,* 2018; WWAP, 2015).

In many countries, environmental flow allocations continue to be used as a surrogate for the protection of Indigenous Peoples and Local Communities' interests in water management (e.g., NWI, 2004; DoW, 2006), with little or no consideration for IPLC customary rights of freshwater resources in water allocation decisions (Finn & Jackson, 2011; Bark *et al.,* 2012; Jiménez *et al.,* 2015). Low representation of IPLCs in water resource decision-making has often led to conflicts and disagreements over values and management priorities, which have often been aggravated by clashes between market-based instruments and local customary rights (Boelens & Doornbos, 2001; Boelens & Hoogendam, 2001; Trawick, 2003; Jiménez *et al.,* 2015) (Also see Supplementary Materials 6.3).

This section presents both short and long-term options for decision makers that contribute to integrated approaches to freshwater governance **(Table 6.5)**.

6.3.4.1 Improving water quality

***Setting clear water quality standards*:** Improved water quality standards are essential to protect both nature and human health, by eliminating, minimizing and significantly reducing different streams of pollution into water bodies (SDG6) including river basins **(Figure 6.4)**. Command and control regulations such as end-of-pipe control, quality standards and discharge permits have a significant role to play to reduce point source pollution (e.g., wastewater from households, commercial establishments and industries) (Kubota & Yoshiteru, 2010; UNEP, 2016; OECD, 2017; WWAP, 2017; WWAP, 2012). A strong and transparent implementing authority with necessary technical and managerial capacity as well as provisions on access to information that benefits implementation and enforcement processes would benefit such regulatory measure (UN-Water 2015b). In addition, mitigation of the impacts of pollution from non-point or diffuse sources (e.g., run-off from urban and agricultural land) requires ecological responses,

Table 6 5 **Options for integrated approaches for freshwater governance.**

Short-term options	Long-term options	Key obstacles, potential risks, spill-over, unintended consequences, trade offs	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Improving water quality					
Setting clear water quality standards; data gathering & monitoring		• Identification of non-point sources • Lack of managerial and technical capacity	National sub-national and local government, private sector, IPLCs, civil society	National, sub-national, local	Institutions, governance, technological
Collaborative initiatives and IPLC monitoring		• Lack of adequate monitoring; • Lack of adequate or effective remedial action	Global, regional, national government, private sector, IPLCs, civil society, donor agencies, science and education organisations	All	Institutions, governance
Technological advances		• Lack of quality standards • Lack of institutional and financial capacity	Regional, national government, private sector, donor agencies, science and education organisations	All	Economic, technological
Strengthening standards for corporate sector		• Lack of compliance monitoring • Lack of enforcement	Global, regional, national government, private sector, donor agencies, NGOs	All	Economic, institutions, governance
Managing water scarcity					
Water abstraction charge		• Abstraction charge may not reflect the environmental cost and vulnerability of local population	National sub-national, local government; IPLCs, private sector, citizens (households, consumers), community groups, farmers	National, sub-national, local	Institutions, economic, governance, demographic
Restrict groundwater abstraction		• Lack of management plan for groundwater • Lack of (or weak) ownership right of groundwater • Lack of monitoring of data • Lack of policies harmonising groundwater with energy, agriculture and urban development policies	National, sub-national, local, private sector, IPLCs, citizens (households, consumers), community groups, farmers	National, sub-national, local	Economic, institutions, governance. demographic
Water efficient agricultural practices		• Lack of access to water efficient technologies for agriculture and optimized irrigation systems • Lack of technical assistance and finance	National, sub-national, local, private sector, farmers, IPLCs	National, sub-national, local	Technological, institutions, governance, economic
Engaging stakeholders					
Integrated, rights based, and participatory approach to water management		• Weak (or lack of) transparent process to identify relevant stakeholders • Weak provisions to access information by stakeholders • Ineffective participation of all stakeholders including IPLCs • Weak (or lack of) a right based approach to protect water resource • Inadequate regulatory framework to support custodianship and open access	National, sub-national, local government; private sector, civil society, IPLCs, donor agencies, science and education organisations	National, sub-national, local	Institutions, governance, cultural

Short-term options	Long-term options	Key obstacles, potential risks, spill-over, unintended consequences, trade offs	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Use of economic instruments					
Payment for water ecosystem services		• Lack of quantifiable environmental objectives at the watershed level • Lack of evaluation of environmental additionality • Lack of monitoring of ecosystem services outcomes	National, sub-national, local government, civil society, IPLCs, private sectors, donor agencies	National, sub-national, local	Economic, institutions, governance
Improving investment and financing					
Public private partnership		• Ineffective regulation, monitoring • Lack of consideration of ILK and IPLC cultural values	National and local governments; civil society including communities, small farmers, workers, women, and IPLCs. Agribusiness, mining companies, finance capital, and international financial institutions	All	Economic, institutions, governance
Promoting Integrated Water Resource Management					
Fostering polycentric governance		• Fragmentation of instruments and institutions • Complexity of issues • Reluctance to move beyond traditional methods	National and local governments, IPLCs, Civil Society, private sectors	Regional, national, sub-national, local	Economic, governance, institutions
Facilitating integration across sectors		• Acknowledge water-food-energy nexus • Broadening the knowledge base	National and local governments, IPLCs, Civil Society, private sectors	Regional, national, sub-national, local	Economic, governance, institutions, technological
Harness international normative framework		• Lack of compliance and implementation	National and sub-national government	Regional, national, sub-national, local	Economic, governance, institutions
Encouraging transboundary water management					
Implementing international law norms and basin treaties		• Lack of political will • Fragmentation • Lack of funding • Lack of implementing mechanisms and institutions	• Treaty Secretariats • National and Supra-national governments • Non-state actors such as NGOs, private sectors, individuals	Global, international, national	Economic, institutions, governance, regional conflicts
Addressing fragmentation		• Lack of political will • Lack of implementing institutions	Treaty secretariats, National supra-national governments	Global, regional, national	Governance, institutions
Strengthening participatory tools		• Lack of information • Lack of effective consultation and participation; • Weak institutions to promote co-decisions • Lack of monitoring	Treaty secretariats, national and supra-national governments	Global, regional, national	Governance, institutions

and education and awareness programmes (OECD, 2017). A basin wide programme can play a positive role in reducing run-off from agriculture (UNEP 2016; GEO6 Freshwater). Moreover, nature-based measures on water purification, soil erosion, urban stormwater run-off, flood control can effectively promote green infrastructure (WWAP/UN Water 2018; Also see section 6.3.5.3).

***Collaborative initiatives*:** The countries with shared water may develop and enforce water quality standards through international or inter-state agreements (GEO-6 Freshwater, 2017). Agreements managing transboundary water can identify highly contaminated sites, develop and implement remedial action and monitoring, and contribute to measurable improvements in the water quality (GEO-6,

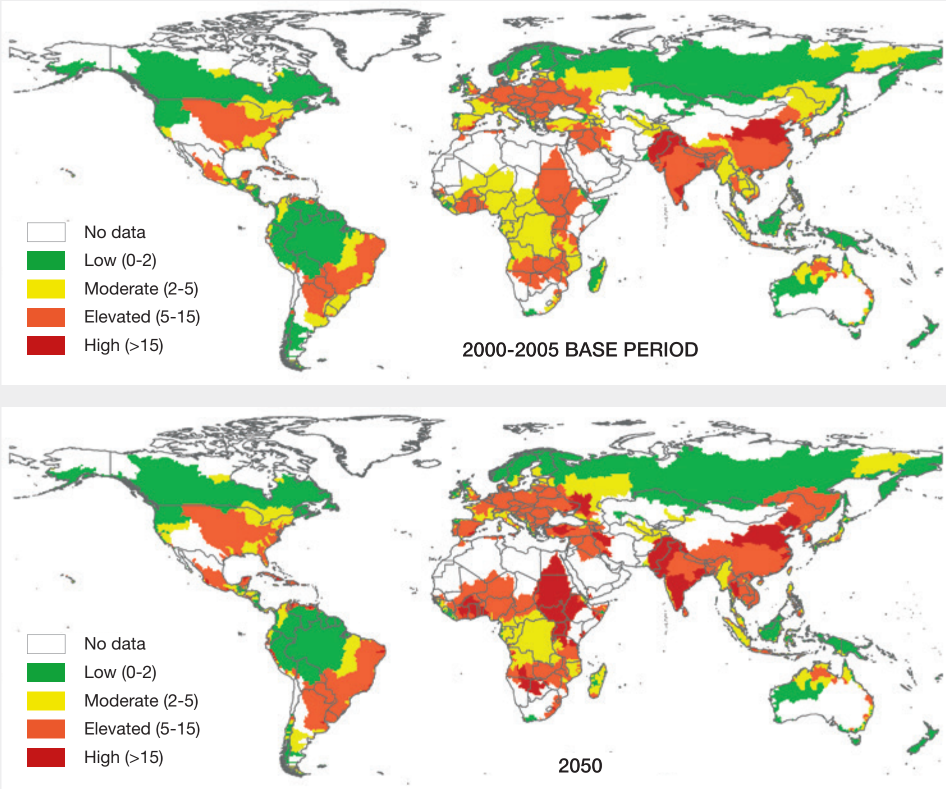

Figure 6 4 **Water quality risk indices for major river basins.**

Water quality risk indices for major river basins during the base period (2000-2005) compared to 2050 (Veolia & IPFRI, 2015, fig.3, p.9).

Freshwater; UNEP, 2016). Well-defined and collaborative international commissions (e.g., Rhine Action programme) or national institutions (e.g., London River Action Plan, 2009) can reduce fragmentation of water management and provide a valuable platform for all relevant actors within the river basin (UNEP, 2016). Such international (e.g., Danube river, Black Sea) and national as well as local collaboration (e.g., 'River Chief' system in China, Wang *et al.,* 2017) to set water quality standards can help ensure that financial resources are spent in the most effective way (UNEP, 2016; WWAP, 2017).

IPLC monitoring: The intimate connection that IPLCs maintain with their freshwater bodies, through intergenerational transmission of knowledge and practices, puts them in a privileged position to closely monitor water quality (Sardarli, 2013; Bradford *et al.,* 2017; see chapter 2.2). In many IPLC worldviews, water is a spiritual resource (e.g., the lifeblood of Mother Earth) that must be respected and kept clean (Mascarenhas, 2007; Collings, 2012; Basdeo & Bharadwaj, 2013; Weir *et al.,* 2013; Morrison *et al.,* 2015). Given that pollution poses important threats to many IPLC livelihoods and cultures (e.g., Orta-Martínez *et al.,* 2007, 2017; Kelly *et al.,* 2010; Harper *et al.,* 2011; Huseman & Short,2012; Nilsson *et al.,* 2013; Jiménez *et al.,* 2015; Bradford *et al.,* 2017) different IPLC groups are engaging, or even initiating community-based monitoring of freshwater quality (Deutsch *et al.,* 2001; Benyei *et al.,* 2017), although evidence on the effectiveness of these initiatives is still largely lacking.

***Technological advances*:** Options targeting the treatment of wastewater and water reuse include pollution prevention at the source (e.g., industries, agriculture), treatment of polluted water, safe reuse of wastewater, and the restoration and protection of ecosystems (UNEP, 2016; WWAP, 2017; WWAP, 2012). The discharge of untreated wastewater can have severe impacts on human and environmental health, including outbreaks of food-, water- and vector-borne diseases, as well as pollution and the loss of biological diversity and ecosystem services (WWAP, 2017). The collection of wastewater and applying appropriate levels of treatment for other uses or discharge into the environment can be improved with quality standards and regulations for incoming wastewater streams and outgoing treated wastewater (WWAP, 2017; OECD, 2017). In addition, it is well established that sufficient institutional capacity and financing are required to build wastewater treatment plants in developing countries and emerging markets (WWAP, 2017).

Data gathering and monitoring: Although there are attempts to gather water related global monitoring data (WWAP, 2017; WWAP, 2012), it is well established that there is a lack of data relating to water quality and wastewater management, particularly in developing countries (UN-Water 2015a) and most notably, in areas inhabited by IPLCs (Nilson *et al.,* 2013; Bradford *et al.,* 2017). Policies that promote holistic assessment of water including gathering of data on water quality and cycle can inform decision-making and increase understanding on how to manage water and ecosystem services sustainably (UNEP, 2016; WWAP, 2012; WWAP, 2015).

Strengthening standards for the corporate sector: There will always be trade-offs between business needs and targets. Better understanding is needed between long-term approaches to meet global goals and short-term approaches chosen by companies. There is opportunity to develop and strengthen voluntary standards that comply with international best practices (e.g., CEO Water Mandate's Integrity Guidelines and Framework, International Water Stewardship Standard, European Water Stewardship Standard), IFC Performance Standards on Environmental and Social Sustainability and SDG6. These voluntary standards aim to enable business and their supply chains to comply with the voluntary standards. Recently, the global corporate reporting standards for water have been revised to measure water consumption and withdrawal in water stressed areas more efficiently (GRI 303: Water, 2018). Such reporting standards aim to enable the corporate decision makers to assess the impacts of their activities on water and how to sustainably manage the resource. Increasing trade of 'virtual water' has led to competition with local water users and exacerbated the need for inclusive and informed water governance (Sojamo *et al.* 2012; Sojamo & Archer 2012). Indeed, several certification schemes include water use and water pollution related issues (e.g., GlobalGap, MPS-ABC, the Rainforest Alliance, IFOAM, Alliance for Water Stewardship). These certification schemes are not without criticisms such as lack of transparency, exclusion of stakeholders, negligible environmental benefits, and poor monitoring. The challenge is to ensure that the certification schemes do not create unequal allocation of water between export-oriented companies and local water users' communities and respect local and customary water rights.

6.3.4.2 Managing water scarcity

Water scarcity is common throughout West Asia and Asia Pacific regions, and in arid parts of Africa and the Americas (GEO-6 Freshwater, 2017). Water scarcity leads to droughts, soil degradation, excessive extraction of groundwater and loss of wetlands with negative impacts on nature and NCP (WWAP/UN Water, 2018; CBD, 2015; Wetlands International, 2010). In the short-term, one option for policy makers is to put water rationing measures to reduce freshwater usage. Water authorities and government may decide to promote water rationing as an emergency measure or as part of a legal water right (GEO6 Freshwater 2017). Option such as water abstraction charge (or water resource management charges) commonly targets industrial users, agriculture, hydropower producers, domestic users and energy production (OECD, 2015), but the charges may not lower water consumption (Finney, 2013; Kraemer, 2003a). To mitigate the negative impacts of any water allocation reform, the decision makers may need to find a balance among divergent interests (Finney, 2013; Rogers, 2002). Abstraction charges for large scale usage of surface and groundwater can be an option to allocate and use water more efficiently. However, such abstraction charge needs to reflect the environmental cost and vulnerability of the local population (Finney, 2013; OECD, 2017b; Kraemer *et al.,* 2003a).

In addition, coherent policy across sectors such as water, energy, climate change and agriculture is needed so that policy reform in one sector does not encourage over-consumption of water resources (FAO, 2014; Bazilian *et al.,* 2011; Olsson, 2013; Benson *et al.,* 2015). In the short-term, e.g., modifications in the land use policy may encourage conservation of water through the use of water efficient agricultural practices, optimized irrigation systems, improved crop varieties, rainwater harvesting and floodwater storage, and discourage agricultural runoff and water loss in the regions with water scarcity (Reddy *et al.,* 2018; OECD, 2015). Greater policy coherence will play a crucial role to reduce negative economic, social and environmental externalities; however, such coherence is vital for better coordination among decision makers and increased collaboration among stakeholders (Rasul, 2016; FAO, 2014; Hussey & Pittock, 2012; Benson *et al.,* 2015).

Option such as desalination of water is used in arid west Asian countries and US (e.g., California) and resulted in increased investment in new desalinization plants (West Asia Regional GEO-6, 2017; North America GEO-6, 2017). Solar desalinization is an alternative that is being applied in several small island states (GEO-6 Freshwater, 2017). There are trade-offs involved as desalination projects require large amounts of energy and 'produces highly concentrated brine' (OECD, 2017) which can negatively affect coastal ecosystems (WWAP, 2017). Thus, the efficiency of the desalinization projects is contested and inconclusive.

Restrict groundwater abstraction: Groundwater abstraction has risen sharply over the last 50 years (Shah *et al.,* 2007) and groundwater pollution has degraded groundwater dependent ecosystems (FAO, 2016a, b; Wada, 2010; Foster, 2013). Surface water and groundwater are closely linked and should be managed conjunctively

(Foster, 2011). It is well established that there is a need for better data regarding existing groundwater resources including their recharge, use and discharge rates (UNEP, 2012; Pandey *et al.,* 2011). As for options, *first*, in the short-term, a management plan on groundwater or both surface and groundwater may clearly set out a framework for groundwater allocation and may contain water quality and salinity management plan (OECD, 2017b; OECD, 2015). *Second*, another short-term approach would be to adopt the rights-based approach to manage water (including groundwater) that may strengthen the provisions on ownership of water, user rights and customary rights, rules related to pollution control and roles and responsibilities of competent authorities (WWAP, 2015; Winkler, 2012; Misiedjan & Gupta, 2014; Mechlem *et al.*, 2016). *Third*, collection and monitoring of data are even more crucial for groundwater management due to the interconnected nature of surface and groundwater and the need for monitoring groundwater abstraction is well established (Custodio, 2002; Konikow, 2005; Shah *et al.,* 2000; FAO, 2016). However, such monitoring will require installation of water meter and tracking of water usage and consumption and monitoring aquifers is technologically demanding and costly (OECD, 2017b; Van Geer, 2006). *Fourth*, groundwater allocation needs to be coherent with policies in other sectors such as energy, agriculture and urban development so that subsidies in one sector do not lead to overconsumption of groundwater (Varady, 2016; Hussey & Pittock, 2012; Alley *et al.,* 2016).

6.3.4.3 Engaging stakeholders

Engagement of stakeholder includes integrated and participatory approach to freshwater management and helps the decision makers to identify innovative and equitable solutions (Varady, 2016). For river basins and water catchments management, multi-level collaborations of government bodies, multi-stakeholder engagement and partnership of various water users at the local level remain crucial (Megdal *et al.,* 2017). Instead of 'top down' policies, it is well established that 'bottom up' policies connecting decision makers and water users promote informed decisions, enhance effectiveness of decisions, and reduce conflicts among water users (Varady, 2016; UNEP, 2016; WWAP, 2017). For example, comprehensive treatment of wastewater is generally undertaken at the local level. Therefore, stakeholder engagement (e.g., through communication, consultation, participation, representation, partnership, co-decision) and motivation for compliance remain crucial for any local policy measure (Akhmouch & Clavreul, 2016). In addition, any such local measure will need to be adapted to economic inequalities, local circumstances, ecosystem needs, competing uses of water and culturally acceptable practices (WWAP, 2017). To increase the use of treated wastewater at the national level, quality standards along with financial or legal incentives can be integrated into national water supply schemes (WWAP, 2017; Hanjra *et al.,* 2015). Consulting with various water users and engaging them in monitoring and performance assessment can help the decision makers to decide the preferred reform options for water management, recognise multiple values and gain a better understanding of the preferences of different waters users (Megdal *et al.,* 2017).

Greater engagement of IPLCs in water governing bodies such as through negotiated agreements (Jackson & Barber, 2015) can serve a purpose in incorporating IPLC social, spiritual and customary values in water management (King & Brown, 2010; Finn & Jackson, 2011; Barber & Jackson, 2012), as well as local ecological knowledge (Weir *et al.,* 2013; Escott *et al.,* 2015). For example, native title law in Australia recognizes Aboriginal rights and cultural values of water, requiring environmental flow requirements for indigenous values in water plans (Jackson & Morrison, 2004; Jackson & Langton, 2011; Jackson *et al.,* 2014). More specifically, adaptive water management regimes have been shown to be effective in accommodating IPLC water entitlements and greater participation of IPLCs in multi-stakeholder water governance (Bark *et al.,* 2012), which may include greater roles of IPLCs in market-based water trading and management mechanisms, where they currently play a minor role (Jackson & Langton, 2011).

Non-governmental organisations can play a role in the formulation of river trusts to protect certain species or pollution event and manage the water catchment (e.g., Severn Rivers Trust in the UK). Success of this type of arrangement depends on the voluntary participation of communities to reach local solutions. Such trust, as a custodian of the waterways, can work with its partners and volunteers to look after the heritage and wildlife on the canals and rivers for present and future generations (e.g., UK Canal and River Trust, 2015).

Along these lines, there is a growing trend towards the recognition of the rights of rivers, as part of a broader movement promoting the rights of nature (Pacheco, 2014; Akchurin, 2015; Díaz *et al.,* 2015; Borràs, 2016; Demos, 2015; Humphreys, 2016). For instance, by granting legal personality to the Whanganui River, the Government of New Zealand found an innovative way to honor and respect the Maori traditional worldviews that see the river as "an indivisible and living whole", as well as the its associated traditional customary institutions for river governance (*Te Awa Tupua (Whanganui River Claims Settlement Act,* 2017; Archer, 2013; Strack, 2017). The legislation recognizes the river as a "living entity" and establishes a co-management regime for collaborative water governance with the Whanganui River Iwi, an indigenous community with cultural ties to the river (Hutchison, 2014; Tanasescu, 2015).

6.3.4.4 Use of economic instruments

There are a range of economic instruments that guide the water sector including tradeable quotas, abstraction charges, payment for ecosystem services (PES), license fees, biodiversity offsets, and subsidies (UNEP 2007; Grafton 2011).

Currently*,* Latin America is the region that counts with more cases of implementation of PES dealing with the protection of watershed services (Brauman *et al.*, 2007; Brouwer *et al.*, 2011; Grima *et al.*, 2017; Martin-Ortega 2013; Stanton *et al.*, 2010). State-led programs constitute the majority of these schemes. Studies assessing the effects of the PES on water flows or quality are basically non-existent, in part due to the methodological difficulties and costs that entail to carry out such type of analyses (Alam 2018; Salzman 2018). Most of PES dealing with water-related ecosystem services are based on empirically untested assumptions about the relationship between land use and the condition and flow of water resources. However, such relationships are complex, and generalizations are difficult to hold (Scott *et al.*, 2004; Sun *et al.*, 2017). Reviews on PES in watersheds have found that most of them are unable to demonstrate impacts on water-related ecosystem services (Brouwer *et al.*, 2011; Yan *et al.*, 2018). In general, the lack of evaluation of environmental additionality is a pervasive problem in PES (Pattanayak *et al.*, 2010), though there have been recent advancements (Jayachandran *et al.*, 2017). The lack of enforcement of conditionality, monitoring of ecosystem services outcomes and evaluation of impacts are reported as recurrent caveats of PES design (Ezzine-de-Blas *et al.*, 2016).

Considerable knowledge gaps still remain with regards to several subjects in PES schemes implemented in watersheds: (a) How to address the uncertainties associated with the relationship between land use and the provision of hydrological services; (b) The extent to which PES schemes are inducing additional effects not only in land use practices but also on the conditions of water resources; (c) How different payment modalities influence rules about the management of common pool resources, such as water; and (d) The long-term relational and behavioural implications of the payments among the involved stakeholders, particularly relations between agents along the watersheds. In addition, the next generation of studies should pay more attention to how to deal with the trade-offs that arise between pursuing ideal design principles, on one hand, and transaction costs and the need to reconcile different policy goals, on the other. Attention should be also given to the profile of PES participants, which has important implications for impact assessment (Grillos 2017; Jack & Jayachandran 2018).

Since the effects of PES schemes on water-related ecosystem services remain largely uncertain, the issue of what can decision makers do to make these interventions effective remain a critical one. *First*, as stated above, impact evaluation systems (and their costs) should be considered in the design of schemes. The establishment of an impact evaluation system should be considered as an inherent part of PES design. Win-win outcomes from PES should not be taken for granted. Indeed, over-reliance on payments as win-win solutions may lead to disappointed results (Muradian *et al.*, 2013). *Second*, in order to enhance legitimacy, the possibility of the existence of multiple values should be acknowledged in the design, implementation and evaluation of PES schemes. The socioeconomic outcomes of the payments might have different meanings to different social groups. *Third*, the assumptions about the relationship between land use and the provision water-related ecosystem services should be derived from empirical evidence. *Fourth*, the management of the scheme should follow adaptive and dynamic principles, based on knowledge generation and incorporation into the design and implementation. Any social-ecological system is dynamic, and the effectiveness of interventions is dependent on the capacity of managers to follow and be responsive to changes.

6.3.4.5 Improving investment and financing

The targets of SDG 6 and the related Aichi Biodiversity Targets (2, 7, 8, 11, 14, 15) require investment in hard infrastructure, such as water- and wastewater- treatment plants, reservoirs, pipes, and sewers; and investment in service systems, including enforceable legal rights, democratic accountability, research and support for local communities and small farmers. The key decision makers for these public goods can be categorized as (A) national and local governments elected by the people of the country; (B) organisations including indigenous and local communities, small farmers, workers, women, and ethnic groups. In parallel there are others pursuing private or market goods, including (C) agribusiness, mining companies, finance capital, and international financial institutions. There are conflicts of interest between these groups in relation to choices for financing investment.

It is well established that investment in wastewater treatment needs to be combined with regulation, monitoring and enforcement (WWAP 2017; OECD 2017a). Leaving ownership and investment to market mechanisms leads to land and water 'grabs', (Woodhouse 2012; Mehta *et al.* 2013), and to price hikes for water and sanitation services (Chong *et al.*, 2006). Thus, business and international financial institutions (group C) have advocated the use of private finance, reinforced by international public sector agencies, to select suitable projects for commercial viability, with public benefits emerging as externalities (Serageldin 1995; Marin 2009; McKinsey 2009). This includes the consistent promotion of Public Private Partnerships (PPPs) as a vehicle for financing investment required for the SDG. PPPs can help incentivize and even co-finance the wastewater sector and promote small- and medium-scale entrepreneurs (WWAP 2017; Murray *et al.*, 2011). However, benefits arising from PPP projects in the water sector are contested and the need to integrate social and environmental considerations in the PPP is well established (Martin 2009; Stringer *et al.* 2018). Sustainable financing for water pollution may benefit from a mix of economic policy instruments that promote an efficient allocation and use of water and reduce water pollution (UNEP 2016)

Actual private investment in water, wastewater and other infrastructure has failed to meet expectations, and has been almost negligible in lowest income countries (Clarke Annez 2006; Foster & Briceño-Garmendia 2010; Gleick 2014; Hall & Lobina 2006). Public sector investment, financed by both tax revenues and utility surpluses, has been the key to development of water infrastructure both in high income countries, including France, and in developing countries, where the MDG for drinking water was met ahead of target (Foss-Mollan 2001; Pezon 2009; Hall & Lobina 2012). For governments and civil society (groups A and B), public finance is more susceptible to democratic accountability and control. Formal techniques, such as cost-benefit analysis, have been used for many decades to evaluate government decisions on investment in water resources, water supply and sanitation (Haveman 1965; Gunter & Fink 2010).

Investment by small farmers, especially with public sector support, can result in more sustainable and biodiversity sensitive investment in irrigation (Xie *et al.*, 2014; Woodhouse *et al.*, 2017; Fraiture & Giordano 2014) and public sector investment in irrigation can successfully reflect economic and resource factors (Rosegrant & Pasandaran 2016), whereas the use of market mechanisms by raising prices impacts farmers' income without improving efficiency (Varela-Ortega *et al.*, 1998). Meanwhile, Natural Capital Accounting could provide an option for the efficient use of scarce natural resources. The WAVES partnership, for example, has supported Botswana, Madagascar and Rwanda to develop accounting methods which include natural capital (Waves Partnership 2013; Stringer *et al.* 2018).

IPLCs have often expressed that engagement in water management is generally limited to consultative capacity through ineffective representative processes (Behrendt & Thompson 2004; Hunt *et al.*, 2009). The development of partnerships optimizing IPLC participation offers substantial opportunities for greater IPLC engagement in water management (Tinoco *et al.*, 2014; Escott *et al.*, 2015; Jackson & Barber 2015). Capacity building relevant to water resources management (Jackson & Altman 2009; Hoverman & Ayre 2012), financial support to allow for participation (Jackson *et al.*, 2009; Escott *et al.*, 2015) and greater consideration of ILK and IPLC cultural values (Mooney & Tan 2012; Nikolakis *et al.*, 2013; Maclean & The Bana Yarralji Bubu Inc. 2015) have been deemed as key enabling factors for fostering effective IPLC participation in water governance (Escott *et al.*, 2015).

6.3.4.6 Promoting Integrated Water Resource Management

Fostering polycentric governance: Particular institutional challenges of catchment-level governance are the reluctance of existing power structures to devolve authority (Jager *et al.*, 2016; Moss 2012; Ring *et al.* 2018) and to move beyond specific pollutants to more systematic governance. Implementation of the Water Framework Directive (WFD) illustrates how many member states have maintained existing structures and procedures while resisting the transfer of power to new river basin authorities (Jager *et al.*, 2016; Ring *et al.* 2018). Failure to implement plans also often compromises the delivery of WFD objectives (Voulvoulis *et al.*, 2017). Implementing polycentric governance remains a key option. For example, the South African National Water Act (1994) aims to adopt a system of polycentric governance at the level of 19 Catchment Management Authorities. While the approach has seen some of the challenges of devolution discussed above, it has been successful in addressing cross-sectoral integration (Muller 2012; Stringer *et al.* 2018).

***Facilitating integration across sectors*:** IWRM enables decision makers to move beyond single-issue policies. Linking land-use and water planning for example has resulted in large urban populations gaining access to water and sanitation (GEO6 H20 chapter; PanEurope GEO6; North American GEO6; LAC GEO6). Understanding telecouplings between distant natural and human systems are an important option for holistic approaches to managing complex socio-ecological systems (Liu 2013; Liu 2015). Consideration of the Water-Food- Energy nexus contributes to taking telecoupling between distant and local drivers of change into account when implementing IWRM (e.g., Stringer *et al.* 2018). In addition, such integration would benefit from the application of social science research to enable greater inclusion of knowledge from policy and political science and public administration and provide important insights into watershed governance (Sabatier *et al.*, 2005; McDonnell 2008; Cook & Spray 2012; Lubell & Edelenbos 2013).

Harness international normative framework: Adoption of integrated watershed, catchment and river basin management strategies is emphasized as one option to maintain, restore or improve the quality and supply of inland water resources (CBD COP Decision IV/4 (1998)). The UNECE Water Convention on the Protection and Use of Transboundary Watercourses and International Lakes (1992) requires parties to take "all appropriate measures" to conserve and restore ecosystems (Article 2). These include the establishment of water quality objectives and criteria, conservation and restoration of ecosystems, and development of concerted action programmes for the reduction of pollution. The Ramsar Convention on Wetlands (e.g., Resolution VIII.16, 2002) also emphasizes the importance of restoration and the inclusion of multiple actors including private landowners, NGOs, and IPLCs in wetland restoration planning and implementation (WWAP-UN Water 2018). A key option for riparian governments and NGOs is to harness the international normative framework to implement national and watershed scale measures. This includes the development of legal instruments and policies for controlling alien species and wetlands restoration – e.g., the Working for Water (WfW) programme pays actors to remove invasive alien species in South Africa while enhancing the capacity and commitment to solve invasive species issues (https://www.environment.gov.za/projectsprogrammes/wfw). (See section 6.3.2.5 for ecosystem restoration).

6.3.4.7 Encouraging transboundary water management

The IWRM options (section 6.3.4.6) are also applicable to the transboundary context. In addition, further options are set out below.

Implementing international law norms and basin treaties: Existing international obligations provide the normative framework and a level playing field for basin level implementation at national and transboundary levels. For example, the UN Watercourses Convention's process-based norms offer options for interpreting and implementing the convention and implementing an effective system at the national level (Rieu-Clarke & Lopez 2013). In addition, basin level treaties can offer effective mechanisms for managing transboundary basins and preventing the escalation or emergence of transboundary disputes (Brochmann & Hensel 2009; Tir & Stinnett 2012; Dinar *et al.*, 2015). The content and design of such treaties need particular consideration (Dombrowsky 2007). For instance, options for securing compliance include strong mechanisms for dispute resolution (UNEP 2002; Lim 2014) and recognition of non-state parties (Jacobson & Brown-Weiss 1998). On the other hand, sanctions are the least effective in terms of implementation across national borders (Brunée 2007).

Addressing fragmentation: Regime fragmentation is a key obstacle of the law of transboundary watercourses (Zawahri 2011; Rieu-Clarke & Pegram 2013) as there is a common trend to adopt bilateral agreements within multilateral river basins (Song & Whittington 2004). The second assessment of the implementation of the UN Watercourses Convention emphasizes the importance of integrating sectorial policies to avoid perverse outcomes (European Commission for Europe 2011). The UN Watercourses Convention and the UNECE Water Convention are the two main international Conventions governing the management of transboundary water resources. Both are in force, open to all countries and mutually reinforcing (McCaffrey 2014). Rieu-Clarke and Kinna (2014) therefore recommend a 'package approach' and three institutional options for States to address fragmentation while simultaneously implementing both Conventions. The first option suggests that the UNECE Secretariat would be responsible for servicing both Conventions. The second envisages two parallel institutional frameworks where each Convention has its own Secretariat. The final option is to maintain the *status quo* where contracting states would not need to make any amendments to the two existing Conventions.

Strengthening participatory tools: Data sharing provisions within transboundary agreements is an important option for enhancing effective transboundary water resource management. Even where data is shared, concerns often remain over their veracity (Turton *et al.*, 2003; Timmerman & Langaas 2004; Grossmann 2006; Armitage *et al.*, 2015; Gerlak *et al.*, 2011). Conversely, data and information can facilitate transparency and trust which in turn enhances compliance (Young 1994; Burton & Molden 2005; Gerlak *et al.*, 2011). In addition, improved stakeholder engagement and enhanced capacity for integrated problem solving are key components of the success of the transboundary endeavor (Dore *et al.*, 2012; Lim 2014). Where stakeholders perceive particular rules to have emerged from a legitimate process, they are more likely to comply with their commitments (Franck 1998; Jacobson & Brown Weiss 1998; Breitmeir *et al.*, 2006; Brondizio & Le Tourneau 2016; Diaz *et al.*, 2018).

6.3.5 Integrated Approaches for Sustainable Cities

Urbanization is one of the most forceful drivers of ecological change (Seto 2013), with more than two thirds of the world's population expected to live in cities by 2050 (United Nations 2010). The most significant growth in urbanization during the 21st century will occur in the developing world, particularly Africa and India, which combined will add more than 1 billion *new* urban residents by 2040 (UNDESA 2014). In urban areas human populations and human built infrastructure are the most dense (Grimm *et al.*, 2008), and can drive significant impacts on local, regional, and global nature and its sustained contributions to people's quality of life if not managed properly (McPhearson *et al.*, 2018). More than half the global urban population lives in settlements of less than one million, and attention is needed across the urban hierarchy, from global cities to towns and small villages (UN Habitat and United Nations ESCAP 2015).

Globally, urban land cover is projected to increase by 1.2 million square kilometers by 2030. This could result in considerable loss of habitats in key biodiversity hotspots, including the Guinean forests of West Africa, the tropical Andes, the Western Ghats of India, and Sri Lanka (Seto *et al.*, 2012), and of Mediterranean habitat types (Elmqvist 2013). Yet despite major changes to ecological properties, critical NCPs are still present in urban settings (Gomez 2013a, Gomez 2013b). An array of options for the protection, adaptive management and restoration of nature in cities are thus critical to maintain a supply of nature's contributions to urban populations and are essential to engender more sustainable futures for city inhabitants (McDonald 2013; McPhearson *et al.*, 2014).

Planning for the impacts of climate change on urban settlements is also a core challenge for our urban future, as highlighted by the inaugural IPCC Conference on Cities and Climate Change in early 2018. Cities consume 75% of the world's energy use and produce more than 76% of all carbon, and are therefore major contributors to climate change, but are also highly vulnerable to risks, especially in coastal locations (Bai *et al.*, 2016). Reducing the impact of climate change will require a more integrated approach to urban design, planning and construction; urban ecosystems; and transport, energy, water and urban governance (Rosenzweig *et al.*, 2016). It will also require implementation by all levels of government – both national urban policy and state and local strategies and actions (OECD 2010), yet many barriers exist that prevent integrated urban approaches, ranging from financial challenges to lack of information to sectoral fragmentation (Runhaar *et al.*, 2018)

The good news is that urban planning and policy in cities around the world are already developing novel approaches, methods, and tools for developing sustainable cities, including in developing countries (Norman 2016, McEvoy *et al.*, 2013, Measham *et al.*, 2011). This section reviews options in the short and longer-term to enable sustainability transitions in cities, while recognizing that the challenges, and thereby the options, differ in the global South and North (Nagendra *et al.*, 2018). The section focuses on the main groups of options for sustainable cities: urban planning for sustainability; nature-based solutions and green infrastructure; reducing the impact of cities; and enhancing access to urban services for a good quality of life (see for an overview **Table 6.6**).

Table 6 6 **Options for sustainable cities.**

Short-term options (both incremental and transformative)	Long-term options	Key obstacles, potential risks, spill- over, unintended consequences, trade-offs	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Urban planning for sustainability					
Bioregional planning		Traditional urban planning that focuses only on development	National & local government, civil society	National, regional, local	Economic, demographic, Institutions, governance
Nature-friendly urban development		Lack of understanding of habitat needs of animals and plants	National & local government	National, regional; local	Institutions, governance
Increasing green space		Trade-offs between densification and green space, increasing land prices	Local government	Local	-
Protecting land for urban agriculture and food security		Zoning that limits urban food production, increasing land prices	Local government, civil society	Local	Cultural
Nature-based solutions and green infrastructure					
Promoting or requiring green roofs to counterbalance temperature effects		Resistance to requiring GI by law, increases in maintenance costs, lack of incentives	National and local government	National, local	-

Short-term options (both incremental and transformative)	Long-term options	Key obstacles, potential risks, spill- over, unintended consequences, trade-offs	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Planting trees to reduce air pollution, mitigate climate change and storm-water control		Trade-offs between densification and green space, concerns about liability and building damage, costs of maintenance	Local government, civil society	Local	-
Protecting watersheds and wetlands for habitat conservation, clean water supply and storm-water control		Trade-offs with other land uses, pressures for development of coastal areas	Regional and local governments	Regional, local	Health
Protecting, creating or restoring wetlands, tidal marches or mangroves for flood protection		Trade-offs with other land uses, pressures for development of coastal areas	Governments	Regional, local	-
Reducing the impacts of cities					
Encouraging articulated density to enable public and active transportation (e.g walking, bicycles)		Trade-offs between densification and green space; changes in lifestyle needed	Regional and local governments	Regional, local	Economic, demographic, cultural, Institutions, governance
Reduce transport energy use through road-use pricing, promoting public transportation		Changes in lifestyle needed, political will to increase taxes on externalities	Governments	National, regional, local	Cultural
Mitigating building energy use by energy-efficient building codes		Resistance to requiring codes by law, costs of retrofitting	Industry, governments	Local	Technological
Addressing urban consumption by encouraging alternative business models		Change in lifestyle needed, planning for circular economy needed	Governments, industry, civil society	All	Economic, Cultural, institutions, governance
Enhancing access to urban services for good quality of life					
Enhancing access to clean water and sanitation, through SUWM, partnerships, investment, etc.		High costs for water infrastructure, concerns about private sector involvement, sectoral siloing	Governments, industry, civil society, private sector	Local, regional	Economic, governance
Improving management of solid waste through incentives & other programs		Difficult to reach informal settlements	Local government, civil society	Local	Economic
Improving access to transportation by investing in public and active transportation		High cost; major shift of focus needed in transportation planning	Governments	National, regional, local	Economic
Encourage participatory planning approaches		Challenges entrenched interests and authorities	Local governments	Local	Governance

6.3.5.1 Urban planning for sustainability

The SDG, UN Habitat (Quito 2016) and the World Urban Forum (Kuala Lumpur 2018) have all collectively reaffirmed the positive contribution integrated strategic urban planning can make in protecting nature within and around cities (Folke *et al.* 2002; Norman, 2018). Over the past few decades, “ecocities” and “green cities” theories began to emphasize the importance of ecosystems within cities and in linked rural areas (Yang 2013). Sustainable urban design seeks to maximize the quality of the built environment and minimize impacts on the natural environment (McLennan 2004). Innovative urban planning theories have emerged, such as Ecological Design (Rottle & Yocom 2011), New Urbanism, Sustainable Urbanism (Farr 2008), Ecological Urbanism (Mostafavi & Doherty 2010), Agricultural Urbanism (De La Salle and Holland 2010), Landscape Urbanism (Waldheim 2007), Green Urbanism (beatley 2000), Biophilic Urbanism (Beatley 2009), Ecocities (Register 2006), and Ecopolises (Ignatieva *et al.*, 2010). These approaches emphasize ecological restoration and connected multifunctional green infrastructure, prioritize walkable and mixed land uses (Register 2006).

Options for sustainable urban planning include: bioregional planning; nature-friendly urban development; increasing green space in cities; and protecting land for urban agriculture (see Supplementary Materials 6.4.1 for a detailed discussion).

- *Bioregional planning:* Inter- and transdisciplinary, collaborative, and strategic urban planning and design that integrates with surrounding regions can offer numerous benefits to water, renewable energy, and air quality (Breuste *et al.*, 2008; Raudsepp-Hearne *et al.*, 2010; Beatley 2011; Colding 2011; Novotny *et al.*, 2010; McDonald & Marcotullio 2011; Pauleit *et al.*, 2011; Ignatieva *et al.*, 2010; Ahren 2013; Carmen *et al.*, 2013; Alexandra *et al.*, 2017).

- *Nature-friendly urban development:* Ecosystems are often highly fragmented in urban areas, which can alter the genetic diversity and threaten long-term survival of sensitive species. To ensure viable urban populations, urban planners need to understand species' needs for habitat quality and connectivity (Kabisch *et al.*, 2017; Braaker *et al.*, 2014; Colding 2011). Ecologically progressive urban planning and policy are already demonstrating how biodiversity conservation and management to enhance local ecosystem services production can be part of urban transitions and transformations for sustainability (Kabisch *et al.*, 2017).

- *Increasing green space and greenbelts throughout cities*: GIS and other holistic spatial planning tools and technologies can be used to create new green spaces and improve and connect existing ones using (Pickett & Cadenasso 2008; Vergnes 2012).

- *Protecting land for urban agriculture and food security*: Urban and peri-urban agriculture, in the form of private gardens, vegetated rooftops, or vertical gardens can both increase food security and conserve biodiversity. Demonstrating that urban agriculture reduces environmental deterioration, increases food security, produces jobs, and connects communities can support rezoning efforts and integration with climate adaptation and flood mitigation policies (Smit 1996; Resource Centers on Urban Agriculture and Food Security).

6.3.5.2 Nature-based solutions and green infrastructure

Increased use of green infrastructure and other ecosystem-based approaches can help advance sustainable urban development while reinforcing climate mitigation and enhancing the quality and quantity of urban NCP (RUAF 2014; Ecologic Institute 2011; Georgescu *et al.*, 2014). The European Commission defines green infrastructure (GI) as "a strategically planned network of natural and semi-natural areas with other environmental features designed and managed so as to deliver a wide range of ecosystem services" (European Commission 2015). Yet, agreement on what exactly constitutes GI is elusive since the term is often used to refer to interventions across a variety of scales including large national ecological networks, wetland restorations, storm-water projects, public green space, allotments, green corridors, street trees, green roofs and walls, permeable pavements and even private gardens (Cameron *et al.*, 2012; Cohen-Shacham *et al.*, 2016).

Green infrastructure can be a critical source for security and improving human wellbeing in urban areas (Gill *et al.*, 2007; Foster *et al.*, 2011; Depietri *et al.*, 2011). Different types of GI can play a role in providing nature's contributions to urban residents such as storm water management and flood protection, temperature regulation, cleaner air and water, urban food production, recreation, and health benefits, as well as contributing to habitat creation and restoration, connectivity of ecological networks, and increasing urban biodiversity (Andersson *et al.*, 2014; Garmendia *et al.*, 2016). GI is also thought to present the most cost effective and synergistic solution for ensuring local climate change adaptation, and promoting low carbon cities (Fink 2016). For example, incorporating green infrastructure in urban design, especially in warmer climates, can potentially reduce the use of air conditioning, increase significant energy savings, and therefore indirectly reduce GHG emissions (Alexandri & Jones 2008; Georgescu *et al.*, 2014).

Specific options for using GI approaches to address urban problems include the following (see Supplementary Materials 6.4.2 for a detailed discussion).

- *GI to counterbalance temperature effects*: The role of some types of GI (trees, green roofs and green walls, parks, ponds) in regulating temperature, including reducing the effects of urban heat islands, is well established.

- *GI for reducing air pollution*: Vegetation can remove or reduce certain pollutants from the atmosphere, including greenhouse gas emissions through carbon sequestration, and trees act as carbon sinks in urban settings (McPherson 1998; McPherson & Simpson 1998).

- *GI to provide clean water supplies*: Provisioning of water is a critical nature contribution to people (NCP) provided by ecosystems and protecting watersheds and wetlands within cities and in the region is crucial. This will also support other regulating NCP including flood alleviation, nutrient cycling, and habitat conservation.

- *GI for storm-water management*: The benefits and cost-effectiveness of GI for storm water and flood control in urban areas are well established (Kabisch *et al.*, 2016).

- *GI for storm and flood control:* A growing number of cases are demonstrating the effectiveness of ecosystems as nature-based solutions to buffer the impacts of climatological, hydro-meteorological and even some geophysical hazards such as landslides (Renaud *et al.*, 2016; McPhearson *et al.*, 2018). The creation or restoration of wetlands, tidal marshes, or mangroves provide water retention and protect coastal cities from storm surge flooding and shoreline erosion during storms (Haddad *et al.*, 2015; Gittman *et al.*, 2014; Kaplan *et al.*, 2009). Similarly, "sponge cities" in China, defined as urban development that takes into account flood control and water conservation through infrastructure planning and ecosystem-based protection, are using GI to combat persistent and significant urban flooding challenges (Li *et al.*, 2017).

Notwithstanding the substantial evidence for the benefits of GI as nature-based solutions, some concerns remain relating to trade-offs, protection of biodiversity, and governance and equity issues. Further research is needed to better understand the synergies and trade-offs between the different benefits offered by GI (Haase, 2015). Promotion of GI at present seems to be focused on opportunities for economic growth, enhancing durability of infrastructure, and cost reduction (Garmendia *et al.*, 2016). GI initiatives would benefit from more explicitly incorporating nature conservation objectives, as well as assessing and safeguarding the impacts of GI projects on biodiversity (Eggermont *et al.*, 2015; Garmendia *et al.*, 2016). A recent EU publication noted the need for habitat suitability and mapping of nature's contributions as part of GI approaches (EEA 2014). In addition, it is also necessary to evaluate the degree of transferability and uptake of GI research within the developing world context, since most research originates in developed countries (Shackleton 2012). Barriers to GI implementation often include a lack of incentives, little institutional support, and concerns about increased maintenance costs (Zhang *et al.*, 2012).

Mainstreaming of GI, and nature-based solutions in general, may include several options. First, meaningful participation from multiple stakeholders is essential in order to identify commonalities and differences between stakeholder preferences (Hansen & Pauleit 2014), and to encourage co-production of initiatives to ensure ownership and stewardship (Nesshöver *et al.*, 2017). Secondly, long-term guardianship of urban areas may require recognition and institutional support for diverse forms of property rights arrangements such as Urban Green Commons (e.g. collectively managed parks, community gardens, allotments) (Colding & Barthel 2013), as well as the empowerment of grass roots initiatives that match solutions to demand (Brink *et al.*, 2016). Lastly, urban planning decision-making processes could benefit from incorporating the concept of the insurance value of ecosystems. This refers to placing importance on the role of nature in conferring resilience that secures the long-term conditions necessary to sustain a good quality of life for humans (Green *et al.*, 2016). This can be applied in an urban planning context to help target investments for GI and urban nature restoration, and might even require involving insurance industry sectors as key investors in GI and nature restoration efforts (European Commission 2015). However, despite the recognition of nature-based approaches as "low regret" measures for climate change adaptation and disaster risk reduction at both local (Kabisch *et al.*, 2017) and global levels (UNISDR 2005, 2015; IPCC 2012), such approaches still remain the most disregarded component of urban plans and strategies (Renaud *et al.*, 2013; Matthews *et al.*, 2015).

6.3.5.3 Reducing the impacts of cities

With global populations urbanizing, the environmental impacts of cities have become increasingly large, such as increasing demand for materials to create infrastructure, vehicles and buildings (IRP 2018). Within this context it is necessary to look at the 'solution space' for cities, noting that some directions for alleviating urban environmental impact are at a national or societal level, and international city-peer organisations such as ICLEI or the C40 collective are sharing experiences among cities on reducing impacts.

The literature on resource efficiency indicates that key issues of concern for urban areas are limited reserves, recycling, and reducing consumption, and from this a systems perspective and circular economy ideas of industrial ecology have emerged (Miatto *et al.*, 2016; Heinz Schandl *et al.*, 2016; Schandl *et al.*, 2015; UNEP 2016). It is worth noting that although thousands of cities report on their (usually only direct) GHG emissions, monitoring of the whole urban metabolism of cities is more rare, but increasing (Kennedy *et al.*, 2011; Huang *et al.*, 2015). Research agencies and NGO are beginning to gather data at the national and international scale, and research indicates that network system modeling approaches, global life-cycle perspectives, and multi-criteria assessments can be key tools (Beloin-Saint-Pierre *et al.,* 2017). Urban environmental assessments will need to become as much a part of planning as housing, transport and economics if we are to measure progress in the resource efficiency of cities. The urban literature points to changes in urban density and form, efficient transport, and how people build, consume, and live in cities as key components to increasing efficiency and reducing impacts (Reid Ewing & Cervero 2010; Reid Ewing & Rong 2008; Weisz & Steinberger 2010).

Specific options for reducing the impacts of cities include the following (see Supplementary Materials 6.4.3 for a detailed discussion).

- *Encouraging density and in-filling:* Sprawling cities generally require more energy for transport per capita (Newman & Kenworthy 1989), more car travel, less travel by public transit (Kenworthy & Laube 1999) and accommodate larger floor area in buildings, which consume more electricity (Kennedy *et al.*, 2015). To be an effective intervention for socio-economic and environmental benefit, density must be implemented at key transport nodes, surrounding and linking between activity centres (Suzuki *et al.*, 2013).

- *Planning urban form and transport:* Planners and industry need to create neighborhoods of mixed land use and diverse housing options that pre-empt the need for citizens to travel across the city (Cervero & Guerra 2011; Ewing *et al.*, 2008; Grubler *et al.*, 2012; Marshall 2008). Other options to reduce transport energy use include internalization of external costs (e.g. congestion pricing), making public transport more attractive, and not extending the road network (Grubler *et al.*, 2012).

- *Mitigating building energy use and emissions*: Buildings are the single largest energy use sector within cities world-wide (Weisz & Steinberger 2010). Significant operational savings can be achieved from implementing energy efficient building codes (Pauliuk, Sjöstrand, & Müller 2013) and with new urbanization and replacement of existing stock, there is an opportunity to decouple energy needs from urban growth (UN Environment and International Energy Agency 2017).

- *Addressing urban consumption:* Reducing the indirect impact of urban consumers can be achieved by promoting the selling of services instead of consumer goods that provide the service. Implemented through the 'circular economy', this collectively can help separate material needs from consumption (IRP 2018) (see further discussion in section 6.4 on sustainable economies).

- *Transformative urban governance:* Engaging citizens in planning, including participatory budgets, is an important role for (local) governments (Grubler *et al.*, 2012; IRP 2018).

6.3.5.4 Enhancing access to urban services for good quality of life

One of the main targets of SDG 11 (sustainable cities and communities) is to ensure access for all to basic services. This is especially urgent in cities in the global South, where inhabitants of informal settlements, or slums, have access to few or no services (Nagendra *et al.,* 2018). Reducing informal settlements was one of the Millenium Development Goals, and more steps can be taken to address these targets to enhance the quality of life for the quarter of the world's population that live in informal settlements (UN-Habitat 2015, Richards 2006). Options include increasing access to clean water and sanitation; improving management of solid waste; increasing access to transportation and green spaces; and transforming governance approaches (see Supplementary Materials 6.4.4 for a detailed discussion).

- *Improving access to clean water and sanitation:* Increasing access to sanitation and clean water by fostering partnerships between all actors to encourage a bottom-up, participatory approach, including recognition of where the informal sector provision of water is working, could increase effectiveness and socio-economic benefits (Ahlers *et al.*, 2014; Annamalai 2016; Bonnardeaux 2012; McFarlane 2008). Sustainable urban water management (SUWM) is the umbrella term for adaptive, integrated, participatory delivery of water, and in most cases, barriers to SUWM are not technical, but institutional (Brown & Farrelly 2009; Marlow *et al.,* 2013). In some cases, public-private partnerships may work, while in others not (Koppenjan & Enserink 2009; Zhong *et al.*, 2008). As noted in section 6.3.4, investing in natural ecosystems such as wetlands can also help to conserve biodiversity while helping communities manage their own water supplies (Postel 2005).

- *Improving management of solid waste:* A top-down approach to improve solid waste management could be integrated sustainable solid waste management (ISSWM) policy, which provides a legal framework to enforce effectiveness (Shekdar 2009). Less costly approaches could be incentive programs and tiered trash collection (pay-as-you-throw) which could significantly reduce the amount of solid waste produced and increase the amount of materials recycled (Dahlen 2010; Folz & Giles 2002) and composting or waste-to-energy programs in place (Sharholy 2008).

- *Improving access to transportation:* Access to safe, affordable, accessible, and sustainable public transportation systems helps communities to thrive socially and economically (Litman 2013; Kenworthy 2006; Litman 2006; Newman 2006; Banister 2001; Deakin 2001; Newman 1999; Cervero 1996; Crane 1996). Other options include promotion of low-cost alternative transportation, such as bicycles or ride sharing.

- *Improve access to green space:* As noted previously, green spaces in cities can contribute to NCP provisioning and biodiversity protection, among other advantages such as increasing GQL, promoting healthy physical and mental well-being (Nadja Kabisch *et al.*, 2017; van den Bosch & Sang 2017; Dennis 2016; Gomez 2013; Lee & Maheswaran 2011), and decreasing crime (Bogar 2016; Donovan 2012; Troy 2011; Kuo 2001).

- *Improving participatory planning and governance for inclusion*: One of the targets of SDG 11 is to enhance and expand on participatory and integrated planning at all levels of governance (UN-SDG 11), which can help contribute to GQL. Participatory planning offers views that may otherwise have been neglected (Innes & Booher 2010).

6.3.6 Integrated Approaches for Sustainable Energy and Infrastructure

It is well established that the energy supply sector based on fossil-fuel energy systems is the largest contributor to greenhouse gas (GHG) emissions (IPCC 2014; Bruckner *et al.*, 2014; Van der Voet 2012; McDaniel & Borton 2002). Extraction, storage, transformation and use of energy sources (i.e. the energy, mining and infrastructure sectors) have considerable negative impact on biodiversity and ecosystem services via degrading, fragmenting, polluting and over-exploiting species and habitats, introducing invasive alien species, and contributing to climate change (CBD/SBSTTA/21/5, Jones *et al.*, 2015; McDonald *et al.*, 2009; chapter 2.1). The transition from a fossil-fuel energy based system to renewables has been identified as a necessary action for a sustainable future. This is reflected by SDG 7 (affordable and clean energy), aiming to ensure access to affordable, reliable, sustainable and modern energy for all, as well as to increase the share of renewables in the global energy mix (UNDP 2016; CBD 2016; CBD 2017). Nevertheless, to ensure the sustainability of an energy transition, impacts of renewables on other SDG (Nerini *et al.*, 2017) as well as on nature and NCPs – especially trade-offs between renewable energy oriented land uses and nature conservation, also covered by the Aichi Targets – has to be equally taken into account (Santangeli *et al.*, 2016a, b; for relevant SDG and Aichi Targets see chapter 3) (See Supplementary Materials 6.5 for discussion on associated challenges).

As **Figure 6.5** indicates, expansion of energy oriented biomass (biofuel) production has more serious impacts on nature and NCP than solar and wind energy, although regional differences across the globe are significant. Therefore, in this section, biofuels related issues are assessed in more detail while other renewable energy sources (including solar, wind, hydropower and their mixes) are discussed throughout.

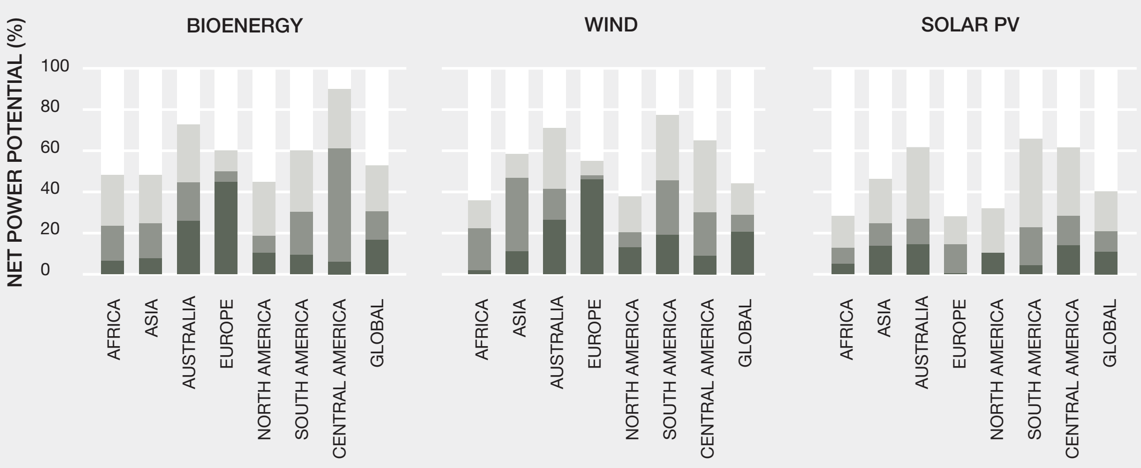

Figure 6 5 **Trade-offs between renewable energy potential and protected areas (Santangeli *et al.*, 2016b).**

Percentage (relative to the total potential of each source) of unrestricted power generation potential available for bioenergy (in the form of *Miscanthus × giganteus*), wind energy and solar photovoltaic summarized by continents and globally. The bars show generation potential within current PAs (Protected Areas; black section of each bar), top ranked areas for 17% PA expansion (dark grey), 17–30% highest ranked areas (light grey) and for the remaining 70% of the landscape (white).

Key governance challenges are the acknowledgement of multiple values in relation to the impacts of current and planned energy use on nature, NCP and GQL, as well as managing trade-offs and telecouplings. Energy use is closely linked to a whole range of political, social and economic interests (Hall *et al.*, 2013; Huber 2013; Mitchell 2011). Institutional interplay across levels – e.g., the course of national borders, the setup of electricity markets, the distribution of property rights, regulations and decision-making processes – defines who owns resources needed for the generation of energy, who gains access to energy, and who bears the burdens (Heindl 2014).

The ways in which energy, mining and infrastructure projects are carried out and implemented trigger conflicts between worldviews and values, raise implementation problems, and often affect IPLC rights to land and water, as illustrated by an increasing number of social-environmental conflicts throughout the world (Arsel & Angel 2012; Rival 2009; Islar 2012; Jordà-Capdevila & Rodríguez-Labajos 2014; Martinez-Allier 2014; Ehara *et al.*, 2016; Spice 2018). At least 40% of all the 2,588 socio-environmental conflicts documented globally happen to involve IPLCs (EJAtlas 2018). Similarly, from the 501 land and environmental defenders that have been assassinated worldwide (2014-2016), almost 40% were IPLCs (Global Witness 2015, 2016, 2017). Disputes over land ownership are an underlying factor in most of these conflicts (Oxfam *et al.*, 2016; Dell'Angelo *et al.*, 2017a, 2017b; RRI 2017). In general, large-scale energy development projects, either renewable or non-renewable, often trigger trade-offs between climate change mitigation, energy provision, social development and nature conservation objectives (e.g., Humpenöder *et al.*, 2018).

Energy production and use are connected by telecouplings to many other ecosystems and resource uses at multiple scales and sectors, raising concerns over biodiversity (e.g., the impact of climate change from energy-related GHG emissions), human health (e.g., the impact of indoor pollution due to inefficient energy technologies), water use and fisheries (e.g., the impact of hydropower), agriculture and forestry (e.g., bio-energy as replacement for fossil fuels), and mining (e.g., rare earth, cobalt, lithium etc. extraction for storage) (Doria *et al.*, 2017).

This section focuses on options for sustainable energy systems exist for various decision makers, including the development of sustainable biofuels strategies, encouraging comprehensive environmental impact assessment, ensuring compensation and innovative financing for environmental and social impacts, ensuring access to energy for all by promoting community-led initiatives, promoting inclusive governance, and promoting sustainable infrastructure **(Table 6.7)**.

Table 6 7 **Options for integrated approaches for sustainable energy and infrastructure.**

Short-term options	Long-term options	Key obstacles, potential risks, spillovers, trade-offs and unintended consequences	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Biofuels strategies					
	Develop sustainable biofuels strategies	• Lack of cross-sectoral policy frameworks • Fragmentation and the lack of coordination between different institutions and sectors • Trade-offs between low GHG energy production and biodiversity	Global institutions, Regional bodies, National and local governments, Private sector, IPLCs	All	Technological, economic
Environmental Impact Assessment					
Improve environmental impact assessment		• Dominance of economic valuation and technical knowledge • Lack of institutional capacity	International bodies, National and local governments, IPLCs	All	Patterns of production and supply

Short-term options	Long-term options	Key obstacles, potential risks, spillovers, trade-offs and unintended consequences	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Compensation and financing					
Strengthen biodiversity compensation policies for development and infrastructure losses		• Compensation does not address root causes of overdevelopment • Difficulties in raising funds in developing countries • Risk for negative impacts on livelihoods by shifting conservation away impacted areas • Ambiguous guidance to developers • Limited capacity for implementation • Inadequate monitoring and enforcement	National, sub-national and local governments, Private sector, IPLCs, Civil society, Landowners and other ecosystem services beneficiaries	National, local	Economic, governance
Promote innovative financing for sustainable infrastructure		• Lack of understanding of novel financial tools (e.g. green bonds and performance bonds) • Concerns about returns of investment • Potential for 'greenwashing'	Global financial institutions National and subnational governments Private corporations	Global, national, subnational	Economic
Community-led initiatives					
Promote community-led initiatives		• Technical and social lock-ins hindering energy independency • Controversial political and economic interests • Energy oligopolies	National governments, Local governments and municipalities, NGOs and cooperatives, Private sector, Citizen and IPLCs	Local, regional, national	Patterns of production and consumption, technological
Inclusive governance					
Promote inclusive governance		• Inappropriate siting of energy infrastructure harming IPLCs • Lack of free, prior and informed consent of IPLCs • Economic interests overruling other aspects	International bodies, National and local governments, Private sector, IPLCs	All	Governance, cultural
Sustainable infrastructure					
	Promote sustainable infrastruc-ture & technology	• Lack of institutional capacity • Lack of economic power • Lack of political will	National and local governments, Universities, Private Sector	All	Technological Patterns of production, supply and consumption

6.3.6.1 Development of sustainable biofuels strategies

Some international organizations (see e.g., IPCC 2014; Searchinger *et al.*, 2017; IRENA 2017), regional organizations (EC 2009) and country governments view biofuel as a clean energy source that support climate mitigation strategies (REN21 2018). Sixty-four countries are in the process of mandating or increasing mandated blending of biodiesel or ethanol in motor fuels, being Brazil, EU, Argentina, Canada and China the largest markets (Edenhofer *et al.*, 2011; IPCC 2014; UN General Assembly 2015; IEA & OECD 2013; Gota *et al.*, 2015; Malins 2015). Favourable taxation and export levies are applied by several countries (e.g., Brazil and Indonesia). Global subsidies for liquid biofuels exceeded US$20 billion in 2014 (Worldwatch Institute 2014). The adoption of biofuel policies has decelerated worldwide but current policies still tend to underestimate risks of biofuels (Goetz *et al.*, 2017; Le Bouthillier *et al.*, 2016; De Man & German 2017; Oliveira *et al.*, 2017; Fargione *et al.*, 2008 – see Supplementary Materials 6.5.1).

At the international and national level, incorporating sustainability criteria in renewable energy laws can recognize the interlinkages between energy use and production, and its impacts on biodiversity (Le Bouthillier *et al.*, 2016; Fritsche & Iriarte 2014; Lin 2012; Frank *et al.*, 2013). For example, the EU Renewable Energy Directive (EU 2009) sets a mandatory 10% minimum target for the share of biofuels in transport petrol and diesel consumption by 2020 to be achieved by all Member States, but to mitigate telecoupling effects it also requires biofuel production to fulfil several sustainability criteria. Options for national governments to mitigate risks of land use change and biodiversity loss related to the expansion of bioenergy production include monitoring and reporting with a focus on potential regulation (e.g., water competition in South Africa), as well as corrective action (e.g., adjustment of the volume of renewable fuels mandated such as in the US and EU). Creating country-wide zoning (e.g., Brazil, Mozambique) can serve as basis of selecting "marginal" or "waste lands" for biofuel production (e.g., India, MNRE 2009), although this is contested in literature (Goetz *et al.*, 2017; Montefrio & Dressler 2016; Baka 2013), especially because such categories, many of which are inherited from colonial occupation, represent rich ecosystems that provide multiple NCP, locally and regionally (Ahmed *et al.*, 2017). Sector-specific zoning (e.g., Brazil's Agroecological Zoning for Sugarcane) and regulation is another option to improve sustainable energy use, which can be interlinked with infrastructure policies. Private sector recently used to implement codes of conduct (e.g., Brazil's Agro-environmental Protocol of the Sugar-based Ethanol Sector) and certification systems (e.g., Indonesian Sustainable Palm Oil), as well as environmental impact assessment and management procedures. However, the current performance of such certifications remains poor, due to the proliferation of low-quality ecolabels and the low market share of certified crops; but also, because ecosystem services and broader cross-sector repercussions of biofuels production and use are not part of such schemes (Gasparatos *et al.*, 2018; German *et al.*, 2017).

Second and third generation biofuels (non-edible plant biomass and unicellular photosynthetic microorganisms, respectively) are promoted as possible alternatives to edible plant based biofuels (Ravindran *et al.*, 2016; Lackner 2015; Mohr & Raman 2013). However, assessments about their effects and associated risks are largely theoretical and premature until these technologies are applied widely (Goetz *et al.*, 2018; Ravindran *et al.*, 2016; Lackner 2015; Mohr & Raman 2013). Second generation biofuels are confronted with sustainability problems similar to those of the first generation (Mohr & Raman 2013). Third generation biofuels (e.g., microalgae) seem to employ significantly less land resources for their production, but their production is very energy intensive and economically unviable today. Technological innovation aims to improve processing technologies as well as microorganisms, pointing to additional risks in form of genetic engineering (Ravindran *et al.*, 2016; Lackner 2015).

For any generation of biofuels to be sustainable, global demand would have to be reduced, and opportunity costs compared to other technologies considered (e.g., photovoltaic, Searchinger *et al.*, 2017). Several governments plan to replace gasoline powered engines by electric ones in the near future to achieve the targets set in the Paris Climate Agreement, which could massively reduce the demand for ethanol and biodiesel. However, advancing e-mobility would amplify other problems, e.g., the production of lithium and other metals and rare earths (Xiong *et al.*, 2018), and expanding it to shipping and air transport (including military) is questionable. Reducing transport volumes, e.g., by shorter supply chains, local production and better public transport, is another option, which would however require far-reaching reforms of the taxation and subsidy system.

6.3.6.2 Encouraging comprehensive environmental impact assessment (EIA)

In the context of energy, the purpose of an environmental impact assessment (EIA) is to assess how the project might cause harm to the environment and to the people and their livelihoods through extraction and infrastructure development. EIA in the mining sector is encouraged worldwide by national laws and international financing organizations (IFC 2012; Equator Principles 2013). While EIA is integrated within the national laws of countries around the world (Morgan 2012; UNEP 2018), case studies demonstrate that social and ecological impacts, IPLC participation, mitigation measures as well as post-monitoring of renewable energy projects may not be adequately addressed in the EIA (Fearnside 2014; Larsen *et al.*, 2018; Schumacher 2017) and weak implementation of EIAs remains a challenge (European Commission 2013). Numerous well established impact assessment methods can be considered helpful for incorporating diverse value systems in the EIA process concerning energy. For example, biodiversity-inclusive EIA offers opportunities for effective participatory mechanisms engaging those who depend the most on nature and its contributions, such as Indigenous Peoples and Local Communities (Akwé: Kon Guidelines 2004; IFC 2012, Standard 7); however, there are associated challenges particularly in developing countries (Craik 2017; Quintero 2012). EIA may also serve as background for "no net loss" and "net gains" biodiversity policies (IFC 2012, Standard 6) using compensatory mechanisms (e.g., offsets), in response to impacts identified in the EIA.

Different options exist to improve EIA practice for energy, mining and infrastructure. Applying the precautionary principle to EIA requires decision makers to identify areas of uncertainty and to consider the implications of knowledge gaps (CBD EIA Guidelines, para. 42). Another option is to incorporate adaptive management into EIA instruments via requirement for ex-post monitoring and follow-up measures (CBD EIA Guidelines, para. 44). Integrating ecosystem services into EIA helps managing trade-offs if implemented in a context-specific manner, by providing a basis to prioritize certain functions and benefits and to identify a wider range of stakeholders affected by potential changes to ecosystem services (OECD 2008; Landsberg 2011; Baker *et al.*, 2013). Such approaches are emerging in EIA practice (European Commission 2013; IFC 2012, Standard 6), but different environmental assessment contexts, resource availability, local capacity and accessible information are likely to drive such integration of ecosystem services (Baker *et al.*, 2013).

Strategic environmental assessment (SEA) has been introduced to expand the scope of impacts by looking at the cumulative effects from programmatic or other spatially related actions (Abaza *et al.*, 2004; UNEP 2018). Challenges aside, widening the scope is possible by incorporating ecosystem services (Slootweg *et al.*, 2010; Geneletti 2013; Landsberg *et al.*, 2013; European Commission 2013; Baker *et al.*, 2013) or integrating Health Impact Assessment with SEA. At present, there is very limited consideration of health in SEA (e.g., in Scotland, Douglas *et al.*, 2011), although good examples exist, e.g., the assessment of health impacts of wind power (Knopper & Ollson 2011; Van den Berg 2003; Pedersen *et al.*, 2004), and the use of the Integrated Environmental Health Impact Assessment approach (Briggs 2008; http://www.integrated-assessment.eu/). See Supplementary Materials 6.5.2 for a detailed discussion on IEA.

6.3.6.3 Ensuring compensation and innovative financing for environmental and social impacts

Compensation approaches have been developed as an instrument to deal with environmental and social effects that cannot be fully avoided or mitigated in energy, mining and infrastructure projects (Koh *et al.*, 2017). Since the 1970's, several countries developed laws and regulations to apply compensatory measures as a requirement for environmental licensing (Rundcrantz & Skärbäck 2003; ten Kate *et al.*, 2004; Rundcrantz 2006). Many compensation approaches are driven by requirements for 'no net loss' of biodiversity – applied now in more than 80 countries – but goals are often challenged by unclear definitions of the baseline reference for 'no net loss' (Maron *et al.*, 2018). Compensation can take form of measures to reduce environmental impacts, to improve social conditions, or monetary payments to offset ecological losses (Villarroya & Puig 2010; Gastineau & Taugourdeau 2014). Recent trends include projects for compensatory mitigation, biodiversity offsets, mitigation banking, habitat banking, species banking, and wetlands mitigation (OECD 2016) (see Supplementary Materials 6.5.3 for a detailed discussion).

There are potential positive effects of compensation schemes, e.g., making new financial resources available for conservation (estimated at several billions per year), reducing the costs of environmental compliance, and supporting the social and economic development of local populations (ten Kate *et al.*, 2004). International experience suggests that no net loss policies combined with biodiversity offsetting and banking can be effective at involving the private sector in conservation, especially relative to widespread uncompensated losses of biodiversity from development projects (ten Kate *et al.*, 2014; OECD 2016; Vaissière *et al.*, 2016). However, there is little comparable data about the amount of compensatory measures and resources allocated for this approach (Villarroya & Puig 2010; Xie *et al.*, 2013). They are intended to be a 'last resort' option, but critiques note that offsets do not address the root causes of overdevelopment of energy, mining and infrastructure projects leading to nature deterioration, and scarcity can create value in markets and banks (Spash 2015). Only a handful of studies have investigated the local impacts of offset projects on IPLCs, which remains a research gap (Bidauda *et al.*, 2017), given that developers who buy offsets tend to be more powerful actors than impacted IPLCs (Apostolopoulou & Adams 2017) and some localized and site-specific biodiversity losses can be irreplaceable (ICMM & IUCN 2012) There is also little literature on the effective use of resources, which makes the results of improving social and economic conditions within project areas inconclusive.

Risks and challenges (see Supplementary Materials 6.5.3) must be addressed for offsetting to deliver on its promise, including the lack of clear policy requirements that offer unambiguous guidance to developers and offset providers (e.g., Quétier *et al.*, 2014), inadequate monitoring and enforcement and lack of political will to require and enforce best practice in offsetting (IUCN 2014; ten Kate & Crowe 2014). More participatory processes of offset definitions and politics have been proposed to address these challenges (Mann 2015).

Standards and obligations for environmental performance or liability in infrastructure and development can mobilize significant amounts of private capital. Innovative mechanisms like performance bonds (whereby a sum of money commensurate with the estimated cost of site rehabilitation is held by a banking or insurance institution to be relinquished upon satisfactory end of the project) are recommended to encourage biodiversity protection during resource extraction, and to ensure sufficient financial sources to restoration after resource extraction activities end (ICMM 2003, 2008). Another new mode of private financing are green bonds, a US$694bn market in 2016, with notably increased use in Asia (Climate Bond Initiative 2017; Clapp 2018). Green bonds raise capital to finance climate-friendly projects in key sectors like transport, energy, building and industry, and water (Croce *et al.*, 2011). Institutional investors are expected to be the dominant buyer of green bonds, and they are touted to provide returns comparable to conventional non-green bonds.

6.3.6.4 Ensuring access to energy for all by promoting community-led initiatives

Energy poverty exists both in developing and developed countries and is embedded in the wider socio-cultural, economic and political context, therefore reflects significant inequalities within and across nations (Brunner *et al.*, 2018; Monyei *et al.*, 2018; Sadath *et al.*, 2017). Citizen's inclusion to renewable energy production and distribution provides more affordable and just energy access, contributes to behavioural change towards more sustainable energy consumption and helps to reduce the adverse impacts of energy use on nature and NCP (Schreuer & Weismeier-Sammer 2010; Rijpens *et al.*, 2013; Kunze & Becker 2015; Islar & Busch 2016). Different types of community-led energy initiatives have emerged all over the world, providing access to clean, reliable and affordable energy. Energy autonomy, realized through decentralized renewable energy production and consumption in local communities and often driven by social and technological innovation to match demand and supply, has been targeted by sustainable and local low-carbon communities in Europe and beyond (Rae & Bradley 2012; Yalçin-Riollet *et al.*, 2014; Hobson *et al.*, 2014; Lee *et al.*, 2014; Hoicka & MacArthur 2018).

Low-carbon communities can take various organizational forms and renewable energy cooperatives (REC) represent a major type which builds on the democratic governance of renewables and provides economic payback to members who join RECs and invest in renewables (Herbes *et al.*, 2017; Hentschel *et al.*, 2018; Heras-Saizarbitoria *et al.*, 2018). Major technological solutions to provide accessible energy to communities in isolated regions include, among others, small-scale photovoltaics (Menconi *et al.*, 2016; Monyei *et al.*, 2018), run-off river hydropower (Egre & Milewski 2002; Wazed & Ahmed 2008), and mixes of different renewable energy sources (Kaldellis *et al.*, 2012). Off-grid, micro-grid and hybrid solutions, applied together with smart technologies, are efficient ways of producing, storing and sharing renewable energy within communities (Menconi *et al.*, 2016). Financing such developments and system transitions may build on public financing and incentives to increase citizen investment (e.g., feed-in tariffs) (Curtin *et al.*, 2017), market based investments (Linnenluecke *et al.*, 2018), and alternative financial models like co-operatives or crowd-funding (Gezahegn *et al.*, 2018; Hall *et al.*, 2018; Vasileiadou *et al.*, 2016). Realizing the urgency of providing modern energy technology and services has also prompted development institutions, such as World Bank and UNDP, to support renewable energy facilities led by communities (UNDP 2012).

Although community-based renewables tend to be less detrimental than large-scale energy development projects as induced land use change is of lower scale and intensity, they might have adverse effects on nature and society (see e.g., Castán Broto *et al.*, 2018; Islar 2012; Aksungur *et al.*, 2011), which has to be mitigated. Overcoming the financial, infrastructural, institutional, socio-cultural barriers of community based renewables is possible if supporting policy is combined with transformation management (Goddard & Farelly 2018), and if governance engages actors from different decision-making levels (Markantoni 2016; Goldthau 2014) and vulnerable groups like women and IPLCs (UNDP 2012) (See Supplementary Materials 6.5.4).

6.3.6.5 Promoting inclusive governance in planning and implementation of energy and infrastructure projects

Excluding local inhabitants from planning energy, mining and infrastructure development projects often leads to socio-environmental conflicts (Finer *et al.*, 2008, 2015; Filho 2009; Kumpula *et al.*, 2011; RAISG 2016; Wilson & Stammler 2016) and legal disputes, coming with severe financial and reputational risks for both states and corporations (Nielsen 2013; Greenspan *et al.*, 2014; Wilson & Stammler 2016). Large-scale infrastructures are often planned and implemented without the Free, Prior and Informed Consent (FPIC) of IPLCs (Hope 2016; Dunlap 2017; MacInnes *et al.*, 2017; Fernández-Llamazares *et al.*, 2018), generally resulting in habitat and biodiversity loss and threatening local livelihoods and good quality of life (Muradian *et al.*, 2003; Escobar 2006; Finley-Brook 2007; Araujo *et al.*, 2009; Finer & Jenkins 2012; Athayde 2014; Laurance & Burgués-Arrea 2017). For example, the rights of Indigenous Peoples in voluntary isolation and initial contact are under assault from infrastructure expansion (Finer *et al.*, 2008; Martin 2008; IACHR 2013; Pringle 2014; Kesler & Walker 2015).

Increased public scrutiny of the social-environmental impacts of extractive activities has led industry to adopt a diverse set of voluntary CSR instruments, including the Extractive Industries Transparency Initiative, the UN Guiding Principles on Business and Human Rights, the Free Prior and Informed Consent, or the Social License to Operate (SLO) (Prno & Slocombe 2012; Business Council of British Colombia 2015; Moffat *et al.*, 2016; Bice 2014). SLO refers to the outcome of engagement processes between industry and communities to establish acceptance of extractive activities (Nielsen 2013; Boutilier & Tgompson 2011), and become central in defining what levels and kinds of social and environmental harm are acceptable, what actions for compensation or restoration are appropriate, and how responsibilities for these actions are distributed (Meesters & Behagel 2017; Idemudia 2007). The concept, however, does not indicate when a SLO is in place, nor does it necessarily imply consent, legitimacy or responsibility of mining activities (Owen & Kemp 2013; Boutilier 2014).

Environmental justice movements, including different forms of IPLC activism, are gaining prominence in response to the expansion of infrastructure development and extraction activities onto IPLC territories (Martínez-Alier *et al.*, 2010, 2014, 2016; Petherick 2011; Athayde 2014; Spice 2018). Mainly through global citizen action, social mobilization and capitalizing on modern technologies, the local social-ecological struggles of IPLCs become matters of global concern (Earle & Pratt 2009; Lorenzo 2011; Temper & Martínez-Alier 2013; Pearce *et al.*, 2015; Januchowski-Hartely *et al.*, 2016). International human rights law protects the right of IPLCs to give or withhold their Free Prior and Informed Consent in relation to resource extraction, infrastructure or energy development projects in their territories (Cariño 2005; Edwards *et al.*, 2011; Ward 2011; MacInnes *et al.*, 2017). Such principle is best understood as an expression of the right to self-determination of IPLCs (Charters & Stavenhagen 2009; Hanna & Vanclay 2013; Doyle 2015) and is enshrined in the UN Declaration on the Rights of Indigenous Peoples, ILO Convention 169, and the Nagoya Protocol on Access and Benefit Sharing, as well as in several national laws (Ward 2011; MacInnes *et al.*, 2017). Although the implementation of FPIC faces several challenges on the ground (Anaya 2005; Perreault 2015; Pham *et al.*, 2015; Dehm 2016), its legal significance is gaining global recognition and lays a solid foundation for simultaneously supporting nature conservation and human well-being (Page 2004; Magraw & Baker 2006; FPP *et al.*, 2016). Increasing engagement of IPLCs in project planning, consultation or social impact assessment is likely to be best served by the adoption of standards and policies such as the Equator Principles, the Global Reporting Initiative, or the UNEP's Policy on Environmental Defenders (Lane *et al.*, 2003; FPP 2007; Yakovleva *et al.*, 2011; UNEP 2018) and binding instruments such as the Escazú Agreement on environmental rights in Latin America and the Caribbean (ECLAC 2018).

A convergence of demand-driven leverage is likely to improve the regulatory stringency and enforcement in countries supplying key mineral resources. For example, in the conflict between IPLCs in Orissa State, India, and the bauxite mining operations of Vedanta Resources (Razzaque 2013), environmental activism, human rights protests and court cases remained ineffective for years, until important shareholders (e.g., the Church of England and the Norwegian government) decided to disinvest in the company, and the government withdrawn the clearances of the mining project (Goodman *et al.*, 2014; Iyer 2015). This case also highlights the possible role of shareholder activism in promoting inclusive governance for energy, mining and infrastructure development (Cundill *et al.*, 2017; Goranova & Ryan 2014). See Supplementary Materials 6.5.5.

6.3.6.6 Promoting sustainable infrastructure

Due to an unprecedented explosion of infrastructure development, extensive areas of the planet are being opened to new environmental pressures (van Dijck 2008; Balmford *et al.*, 2016; Johansson *et al.*, 2016; Gallice *et al.*, 2017; Kleinscroth & Healey 2017) as part of massive infrastructure-expansion schemes—such as China's One Belt One Road initiative (Laurance & Burgues 2017; Lechner *et al.*, 2018) and the IIRSA program in South America (Laurance *et al.*, 2001; Killeen 2007). These new "development corridors", including roads, highways, hydroelectric dams and oil and gas pipelines come with high environmental and social costs, including deforestation (Barber *et al.*, 2014; Fernández-Llamazares *et al.*, 2018), biodiversity loss (Laurance *et al.*, 2001, 2006, 2008; Pfaff *et al.*, 2009; Benítez-López *et al.*, 2010; Sloan *et al.*, 2017), land grabbing (Toledo *et al.*, 2015; Alamgir *et al.,* 2017), social disruption (Mäki *et al.*, 2011; Baraloto *et al.*, 2015) and violation of IPLC customary rights (Fernández-Llamazares & Rocha 2015; Martínez-Alier *et al.*, 2016; Delgado 2017).

The total length of paved roads is projected to increase globally by 25 million kilometres in 2050 (Dulac 2013), with nine-tenths of all road construction occurring in developing countries (Laurance *et al.*, 2014). Given that new roads generate large ecological footprint (e.g., Laurance *et al.*, 2002, 2009), a viable and cost-effective way to avoid habitat loss in areas of high conservation value, also including protected areas, is to keep them road-free by "avoiding the first cut" (Caro *et al.*, 2014; Laurance *et al.*, 2014, 2015; Alamgir *et al.*, 2017; Sloan *et al.*, 2017; Fernández-Llamazares *et al.*, 2018). Another vital tactic is to use large-scale, proactive land-use planning. Approaches such as the "Global Roadmap" scheme (Laurance & Balmford 2013; Laurance *et al.*, 2014) or SEA (Fischer 2007) have been successfully used to evaluate the relative costs and benefits of infrastructure projects, and to spatially prioritize land uses to optimize human benefits while limiting new infrastructure in areas of intact or critical habitats (e.g., Laurence *et al.*, 2018; Laurance *et al.*, 2015; Balmford *et al.*, 2016; Sloan *et al.*, 2018).With many roads becoming rapidly dysfunctional, investing in maintenance represents a more sustainable option than road expansion (Wilkie *et al.*, 2000; Burningham & Stankevich 2005; Luburic *et al.*, 2012; Alamgir *et al.*, 2017).

Infrastructure development related to renewable energy sources can adversely affect nature and humans, decreasing the net benefits and sustainability of renewables (Drewitt *et al.*, 2006; Cohen *et al.*, 2014; Lang *et al.*, 2014; Drecshler *et al.*, 2017). Life cycle assessment can help decision makers choose the best renewable energy source for specific purpose. Along with

EIA or SEA, a landscape approach using geographical information systems can be applied to compare the impacts of different energy scenarios on nature and NCP, by integrating various types of data (Benedek *et al.*, 2018; European Commission 2014; Jones *et al.*, 2015). Resource extraction (e.g., rare earth, cobalt, lithium) for assembling electrical components of renewable energy production, especially batteries and photovoltaics, will further increase and affect the environment (Fthenakis 2009; Larcher & Tarascon 2015). Sustainable mineral sourcing could be improved via global governance which sets and monitors international targets (Ali *et al.*, 2017). Geological exploration plans considering the overlap between protected areas and the prevalence of mineral resources (e.g., the MiBiD index) could further decrease the impact of mining on nature (Kobayashi *et al.*, 2014). Similarly, the negative impacts of energy-related infrastructure can be mitigated through the use of land-use zoning to identify sensitive areas (e.g., Laurance *et al.*, 2015; Balmford *et al.*, 2016; Sloan *et al.*, 2018) or through sensitive operating practices – e.g., turning off wind turbines when large numbers of soaring migratory birds are passing (Hüppop *et al.*, 2006; Allinson 2017).

Dams – producing hydropower, improving navigation or providing secure water supply (Nilsson *et al.*, 2005) – also have largescale landscape impacts (e.g., Belo Monte Dam in Brazil, Lees *et al.*, 2016). More than 50,000 dams above 15 m height exist worldwide (Lejon *et al.*, 2009), and several examples point the significant negative impacts they have on nature and society (Tullos 2009; Finer & Jenkins 2012; Fearnside 2016; Dudgeon 2010; chapter 4; Doria *et al.*, 2017; Beck *et al.*, 2012), which are often not well mitigated (Zarfl *et al.*, 2015; Poff & Schmidt 2016; Winemiller *et al.*, 2016; Latrubesse *et al.*, 2017).

Despite their negative environmental and social impacts, dams may generate new benefits (Menzie *et al.*, 2012), such as create habitat for protected species, or function as a refuge under climate change, making it difficult to consider biodiversity trade-offs associated with decisions about dam removal (Lejon *et al.*, 2009; Beatty *et al.*, 2017). While many studies show positive effects of dam removal on biodiversity (e.g., O'Connor *et al.*, 2015), others highlight unintended risks and consequences, such as dispersal of invasive fish (Lejon *et al.*, 2009), colonization of non-native plants (Tullos *et al.*, 2016) or spread of accumulated contaminants (O'Connor *et al.*, 2015). Case studies also show that deliberations about dam removal tend to create situations where locals become divided between environmental, economic, and cultural losses and gains (Reily & Adamowski 2017). In sum, the complex consequences of dam-removal are unresolved, and studies are typically not framed to inform management concerns that are context-specific (Tullos *et al.*, 2016). See Supplementary Materials 6.5.6.

6.4 TRANSFORMATIONS TOWARDS SUSTAINABLE ECONOMIES

The publication of the *IPCC special report on global warming of 1.5°C* made clear that under current development trajectories global warming will exceed 1.5°C during the coming two decades (IPCC 2018). Similarly, it has become evident (this report; UN 2018) that achieving the internationally-agreed 2030 Sustainable Development Goals and the 2050 Vision for Biodiversity will require transformative change towards sustainable economies. This is the context within which progress towards sustainable landscapes, marine and ocean systems, freshwater management, urban systems, and energy and infrastructure are subsumed, and for which they represent vital parts of the solution.

A plethora of definitions for a sustainable economy have been suggested (e.g., King & Slesser 1994; Bartelmus 1999; Pearce & Barbier 2000; Urhammer & Røpke 2013; Pullinger 2014; Martin 2016). In the IPBES context it can be defined as an economy that does not produce the indirect and direct drivers impinging on nature, nature's contributions to people, and a good quality of life, and account for the important role that telecoupling, trade, supply chains, and producer-consumer interactions now play in our global system. This requires that economic, social and technological indirect drivers and the patterns of production, supply, and consumption that make up the economy respect ecological limitations and ecosystem integrity (Raworth 2015; Bengtsson *et al.*, 2018).

A sustainable economy must also provide more equitable access to the fruits of development and quality of life (O'Neill *et al.*, 2018). Some impacts on nature can be caused by poorer households forced to exploit natural resources due to a lack of other economic options, although the poor are often well aware of their dependence on nature and protect biodiversity (Martinez-Alier 2002). Other data suggests that it is inequality in particular that may lead to negative impacts on the environment as wealth concentrates among people who are not willing to pay for the provisioning of public goods (Boyce 1994; Kashwan 2017). Policies aimed at reducing poverty and inequality thus have the potential to be linked up with priorities for NCP conservation (Johnson 1973). Rethinking what makes an economy sustainable thus will need to focus not only on incorporating pluralistic values of nature, as this report has noted, but also rethinking what it means to have a good quality of life, and how it links to nature and its contributions (Naeem *et al.*, 2016). The concept of an "adequate standard of living" as a human right derives from the Universal Declaration of Human Rights (UN 1948). Policies to achieve a "social protection floor" to protect this right include measures and institutional reforms to achieve both basic income security and universal access to essential, affordable social services (UN 2018). These aims could be combined with more nature-specific measures and attention in the 21st century, such as including ideas about access to NCP as part of social protection measures.

Further, a sustainable economy must be one in which climate change causes and impacts are addressed, to ensure that carbon emissions do not remain an environmental externality, that globalization does not exacerbate the impacts of climate change, and that communities have sufficient financial means to reduce vulnerability and adapt to forecasted changes (O'Brien

Table 6 8 **Options for transformation to sustainable economies.**

Short-term options	Long-term options	Key obstacles, potential risks, spill- over, unintended consequences, trade-offs	Major decision maker(s)	Main level(s) of governance	Main targeted indirect driver(s)
Reforming Subsidies					
Assess impacts of all subsidies policies (e.g. energy, fisheries, agriculture, water); removal of cost ineffective subsidies	Long-term removal of all environmentally-unsound subsidies	Vested interests opposed; political challenges: beneficiaries of subsidy policies protest their removal; welfare impacts of subsidy removal for some communities	National; sub-national; and local governments; research & education organizations	National and sub-national	Economic, institutions
Address over and under consumption					
'Nudges' to consumers; product labelling; local reuse or fix-up initiatives; corporate or NGO led initiatives to discourage overbuying; taxes on consumption; consumer reduced-consumption movements	Expansion of sharing economy; transition towns; sufficiency orientation of consumers; design for sustainability for products and services	Beliefs in rationality of markets; dogma of consumer sovereignty; lack of policies that address leakage & telecoupling; political risks for tax increases; potentials for consumer backlashes	Citizens; private sector; national governments; NGOs; scientific groups	National and local	Economic, cultural
Reducing unsustainable production					
Taxes on resource consumption and degradation; circular economy models; use of LCA as policy tool; corporate social responsibility (CSR)	Circular economy; change production systems based on LCA; capping of resource consumption	Lack of data and research on efficacy; market forces promoting growing production; insufficient consumer interest	National, sub-national and local governments; private sector; NGOs	National and local	Economic, cultural
Reforming trade regimes and financial systems					
Changes in trading rules; stricter regulation of commodity futures markets	Reforming trade system & WTO; future regulation on environmental derivatives	Vested interests opposed; complexity and opaqueness of information	National governments; intergovernmental institutions	All	Economic, institutions
Reforming models of economic growth					
Use of alternative measures of economic welfare and Natural Capital Accounting	Move toward steady state economics paradigm and degrowth agenda	Mostly academic exercises so far; lack of clarity on how to achieve steady-state or degrowth; political risks of not supporting economic growth at all costs; initial welfare impact of recession or degrowth; need to reallocate large sector of economy	Global institutions; national governments; private sector	All	Economic, governance, institutions

& Leichenko 2000; Stern 2006; Betzold & Weiler 2017). Failure to act now on reducing emissions is likely to impose severe economic risks to economies around the globe (Stern 2006; Hsiang *et al.*, 2017), yet recent modelling notes the particular challenges of holding warming to 1.5 degrees given strong economic inequality, high dependence on fossil fuels for global trade and transport, and inadequate climate policies (Rogelj *et al.*, 2018). While many policies have as their stated goal a nexus of nature protection, climate mitigation or adaptation, and poverty reduction, successes in this area are still difficult to find (Boyd *et al.,* 2007, Reynolds 2012, Caplow *et al.,* 2011, Lowlor *et al.,* 2013).

This transformation of the global financial and economic system towards sustainability is both necessary and possible, as the current system increasingly reflects dominant power and geopolitical interests rather than a commitment to sustainability and equity. Aichi Biodiversity Target 4 calls for governments, business and stakeholders at all levels to take steps towards "sustainable production and consumption", as does SDG 12 (responsible consumption and production) (Bengtsson *et al.*, 2018) (section 6.4.2 and 6.4.3). International systems of trade and national systems of positive and negative subsidies are also tools for achieving more sustainable ends (section 6.4.1 and 6.4.4). Finally, there are alternative models of the economy (including green growth and degrowth) to achieve a good quality of life without contributing to degradation of nature and nature's contributions to people (see section 6.4.5). There are a number of possible options for decision makers to begin to transform our economic system into a more sustainable one, ranging from immediate short-term options and longer-term options that may take decades or more to implement. Given the size and scope of the global economy, encompassing all levels from local economic output of firms to global trade between nations, different options can be applied at different scales, from individual consumers up to international institutions. This section provides a review of these options **(Table 6.8)**.

6.4.1 Reforming environmentally harmful subsidy and tax policies

Aichi Target 3 calls for the elimination, phasing-out or reform of incentives, including subsidies, that are harmful to biodiversity. It is estimated that financial support to agriculture that is potentially environmentally harmful amounted to USD 100 billion in OECD countries in 2015, and that fossil fuel subsidies account for USD 345 billion globally (OECD 2017a). The amount of finance mobilized to promote biodiversity is therefore conservatively estimated to be outweighed by potentially environmentally harmful subsidies by a factor of 10. Other potentially environmentally harmful subsidies that may also adversely affect biodiversity and ecosystems include those that encourage overcapacity in the fishing and forestry sector, subsidies that encourage urban sprawl, and the over-consumption of water.

Given the magnitude of these harmful subsidies, governments should consider the fiscal and environmental implications of their policies and work to identify and assess both their direct and indirect impacts on terrestrial and marine ecosystems. Many of these support policies were put in place for other reasons, such as to maintain the economic viability of rural areas, but such objectives can be achieved with policies that promote public goods, rather than the over-exploitation of natural resources. Reducing harmful subsidies and increasing positive environmental subsidies allows countries to compensate for the cost of adopting environmentally friendly production and consumption behaviour and by so doing, encourage such behaviour. Examples of positive subsidies with outcomes on biodiversity include grants to farmers who construct contour bunds on steep slopes, which is a policy within both the US Conservation Reserve program and the EU CAP (see **Box 6.5**).

Agricultural subsidy policy reform has already taken place with success in some countries; agricultural subsidies were reformed in Switzerland and New Zealand, and pesticide

Box 6 5 **Positive Subsidies.**

The EU Common Agricultural Policy (CAP) has long tried to use generally voluntary schemes aiming at providing incentives to farmers to conserve and better provision ecosystem services on their individual farmlands and prevent agricultural land degradation (e.g. overuse of pesticides or tillage). Under CAP, farmers are required to make a five-year obligation to use environmentally friendly farming practices (for example, conservation set-asides, organic agriculture, low-intensity systems, integrated farm management; preservation of landscape of high-value habitats and biodiversity, etc. (CDB 2015), and they receive payments to cover the cost of these enhancements or income lost from doing so. However, the agri-environmental payments of the CAP in particular are reported to have only a moderate positive impact on biodiversity (e.g., Capitanio *et al.*, 2016; Overmars *et al.*, 2013; Whittingham 2011; Kleijn *et al.*, 2006; Primdahl *et al.*, 2003) (see Ring *et al.,* 2018, section 6.5.2).

subsidies were removed in Indonesia (OECD 2017c). Subsidy reform can be combined with other measures, for example removing harmful subsidies from livestock production, imposing taxes, and internalizing social and environmental externalities in food production costs (Stoll-Kleemann & Schmidt 2017). However, the full impact of removal of subsidies on biodiversity and nature is not well understood, given the long time-lags necessary to judge such impacts.

In another example, removal of inappropriate subsidies to fossil fuel energy will help reduce carbon emissions. Estimates of the global costs of subsidizing fuels from 2012 to 2015 range between US$300-680 billion per year depending on accounting methods (Franks *et al.*, 2018). G7 countries alone provided at least $100 billion annually in subsidies for the production and consumption of oil, gas and coal, despite pledges from these countries to reduce them (Whitley *et al.*, 2018). Reducing energy subsidies and spending these funds instead on SDG would allow many countries to go a long way towards meeting their domestic financing needs. For example, Vietnam has annual per-capita fuel subsidies of US$35, which would cover an estimated one quarter of funding needed to meet their SDG commitments (Franks *et al.*, 2018) (see **Figure 6.6**). India, Indonesia, and Mexico recently reduced their subsidies for transport fuels, and major reforms of fuel or electricity prices are taking place in Argentina, Egypt, Iran, the Gulf Co-operation States, and Morocco (OECD 2017a; Rosas-Flores *et al.*, 2017; Wesseh *et al.*, 2016; Bhattacharyya *et al.*, 2017). Iran was able to end ecologically undesirable fuel subsidies by instituting a universal dividend while phasing out subsidies (Tabatabai 2012), and subsidy removal can result in opportunities for conservation and potential energy savings, as shown in in Malaysia (Yusoff & Bekhet *et al.*, 2016). China has also recently removed some energy subsidies (Jiang *et al.*, 2015; Lin *et al.*, 2014; Lin & Li. 2012) reporting both economic and environmental gains (Hong *et al.*, 2013). The starting point for energy subsidy reform from these cases points to the need to clearly define the policy objectives, understand the distribution of the costs and benefits of subsidies, assess economic as well as social and environmental impacts, actively promote the dissemination of information to stakeholders, and engage with all relevant parties (Barg *et al.*, 2006).

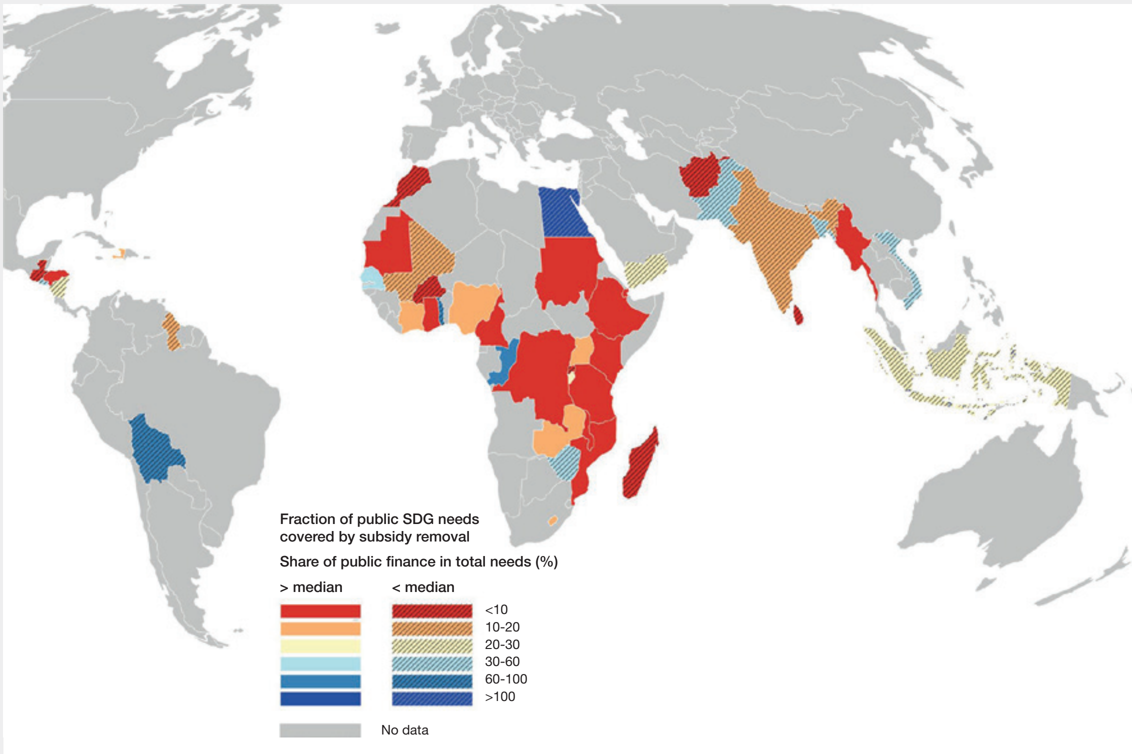

Figure 6 6 **Fraction of the national public investment need for the SDG agenda that could be financed by freeing up funds that are used at present for subsidizing fossil fuels.**

Source: Franks *et al.* (2018).

In the fisheries sector, subsidies have been estimated to be at least 13 billion per year (OECD, 2017b; Sala *et al.,* 2018). Many governments subsidize fishing by national fleets, often exceeding the net economic benefit. Fisheries subsidy reform took place in Iceland, New Zealand and Norway in the 1990s in attempts to reduce pressure on fishing stocks but remains a problem in many other countries and in particular in High Seas fishing. A recent review of High Seas fishing found that without subsidies and low wages (often slave level labor), "more than half of the currently fished high-seas fishing grounds would be unprofitable at present exploitation rates" (Sala *et al.*, 2018) (also see section 6.3.3.3.2).

International action can help countries become motivated to tackle subsidy reform, such as through "informal international law" (Pawley *et al.*, 2012). They include declarations by the leaders of the Group of Twenty (G20), the Group of Seven (G7), and the Asia-Pacific Economic Cooperation (APEC) countries. SDG target 14.6 calls on countries to prohibit certain forms of fisheries subsidies that contribute to overcapacity and overfishing, and Target 12.C makes a similar appeal to phase out "inefficient fossil fuel subsidies". The WTO has more stringent rules, or "hard law" on controlling subsidies in general, and the Agreement on Agriculture has stewarded a gradual reduction in the most trade-distorting support to the farming sector, but none of these address environmental effects specifically. At the global level, there are calls for streamlining positive renewable energy subsidies as well as involving global institutions like the WTO and the UNFCCC in the energy subsidy reform (Cosbey & Mavroidis 2014; Rubini 2012; De Bièvre 2017; van Asselt & Kulovesi 2017; Van de Graaf & van Asselt 2017).

Commonly cited obstacles for subsidy reform include concerns regarding impacts on competitiveness and distributional impacts, including employment. However, ex-post empirical analysis has found little evidence in this regard (OECD 2017c). Vested interests and political acceptability can also present barriers to subsidy reform. Political economy insights from successful biodiversity policy reform can shed light on how this transition can be achieved in practice (OECD 2017c). These suggest the need to: act quickly when presented with windows of opportunity that may be outside the influence of domestic policy makers and unrelated to the environment (for example, human health); build alliances between economic and environmental interests (e.g., when there are common interests between certain groups, even though the motivations may not be); devise targeted measures to address potential impacts on competitiveness and income distribution; build a robust evidence base on the social costs and benefits of reform; and encourage broad stakeholder engagement (OECD 2017c; 2011).

Finally, ensuring compliance with fair tax policies can help ensure funding for biodiversity and nature as well. Tax havens reduce the amount of financing available to governments for global public goods provisioning and provide bad actors with opportunities to avoid financial scrutiny, reducing the impact of policies such as certification or supply chain monitoring (also see section 6.3.2). A recent study of tax havens found that 70% of known fishing vessels implicated in illegal fishing are flagged in a tax haven, and that nearly 70% of foreign capital to the largest companies raising soy and beef in the Amazon, prime drivers of deforestation, was channeled through tax havens (Galaz *et al.*, 2018).

6.4.2 Addressing Over- and Under-consumption

Over-consumption by households is a major driver of resource use and depletion, primarily in housing, mobility and nutrition (Spangenberg & Lorek, 2002). Involuntary under-consumption is synonymous with poverty and a lack of options, while overconsumption results from unsustainable choices and practices. Overconsumption plays a major role in driving NCP loss and is associated with higher carbon footprints (Ivanova *et al.*, 2017). Reduced consumption is thus also an imperative to meet the Paris Agreement climate targets, which are unlikely to be met with resource efficiency or alternative energy sources alone (Alfredsson *et al.*, 2018). Patterns of over-consumption, however, vary greatly within and across global regions, with involuntary under-consumption and poverty representing the reality of a significant portion of the world population.

One basic misperception is that a better life is held to emerge from more consumption opportunities. Instead, studies show human needs are limited and mostly non-material; they can be satisfied with less resource consumption than usual in the affluent countries (Steinberge & Roberts, 2010) if suitable satisfiers are chosen (Max-Neef *et al.*, 1989). Satisfaction with GQL has been shown not to increase above a certain income threshold (Max-Neef 1995) and to be decoupled from income and thus consumption thereafter (Layard 2005; Hoffman & Lee 2016) (although the rich seem to be happier than the poor in most societies (Veenhoven 2010)).

Consumption-focused policies have a significant opportunity to complement other nature conservation efforts (Igoe 2013; Isenhour 2014) with a resource conservation potential of demand-side measures potentially matching supply side options (Cruetzig *et al.*, 2016; Lazarus *et al.*, 2011), in particular when combined with policies to compensate for rebound effects (the phenomenon where increased efficiency leads consumers to take that additional money and increase consumption elsewhere) (Jackson 2005; Lorek & Spangenberg 2014). We here review options for consumers, governments and the corporate sector.

Consumers' action options: Grassroots and civil society organizations have advocated a wide range of lifestyle modifications and shifts in consumer behaviours, often focusing on information and education initiatives for affluent and environmentally conscious consumers, such as generating pressures on corporations and governments by mobilizing the social norms of affluent consumers (Conroy 2001) and engaging in the co-designing of products and services (Fuad-Luke 2008). Critics point out that these successes are often short lived and have done little to challenge dominant consumption logics or practices. Furthermore, studies indicate that changing the composition of consumption has limited effects on the overall environmental impact (Røpke 2001) and that it is reducing the level of resource consumption that reduces drivers of environmental damage (Lorek 2010; di Giulio & Fuchs 2014; Lorek & Spangenberg 2014).

Already a number of consumers have chosen to reduce their consumption by practicing 'voluntary simplicity', often motivated more by lifestyle choices rather than concerns about sustainability (McDonald 2015) and in conjunction with reducing their income and increasing their leisure time and thus avoiding rebound effects (Freire-González *et al.*, 2017). As such changes are not easy in the current consumer society (Speck & Hasselkuss 2015), dedicated policies are called for to make a resource-light, good life easier (Schneidewind & Zahrnt 2014; Heindl & Kanschik 2016).

Government policy options supporting consumers: To influence *conscious decisions,* awareness-raising and information campaigns are viable options. However, the literature on their effectiveness is unclear, particularly for the average consumer who may not share strong environmental norms (Stern 2000; Spaargaren *et al.*, 2013). An option to influence *spontaneous decisions* is the choice architecture approach including nudging, i.e. offering pre-set default options which in some cases had a strong influence on consumers' propensity to make desirable choices (Gsottbauer & van den Bergh 2011). Nudges can include tailored messaging or offer peer comparisons, provide disclosures or warnings, create default rules, or use social norms (Sunstein 2015; Lehner *et al.*, 2015; Halker 2013; Olander & Thorgersen 2014). However, nudging has been effective only if the required change of everyday life routines and the effort required were not too onerous (Keller *et al.*, 2016). There is also very little evidence that non-regulatory measures used in isolation, including nudges, are effective for biodiversity conservation (Newton *et al.*, 2013; Hobson 2013). *Legislation and norms* have the advantage of binding all consumers for all kinds of decisions to the same standards, and to be implementable in relatively short time. They range from broad ecological tax reforms to bans of single-use disposable products, disincentives for travel or meat consumption, and public investments in product service agreements or collaborative consumption networks. Many consumers favor the removal of dangerous products from the market and a stronger role for governmental agencies in protecting consumers over more choice (Isenhour 2011).

Taxing consumption: Many taxes on activities or products exerting negative (and often indirect) effects on ecosystems and biodiversity rely either on the polluter-pay principle or on the user-pay principle (Ekins 1999). Examples of these "green" taxes and levies can include:

- Pesticide taxes, e.g. France, Denmark, Norway, Sweden, United States (OECD 2017a; Hogg *et al.*, 2014). However, moderate increases in the tax rate alone appear not to be sufficient to reduce use (Sainteny 2011; Jacquet *et al.*, 2011).
- Fee-based licenses for logging, fishing and hunting are price mechanisms to limit certain detrimental mechanisms (Fisher *et al.*, 2008).
- Taxes on luxury and consumer goods have shown some success in reducing excess consumption and raising money for other initiatives (Schor 2005).
- Road and congestion charges, often in large cities like London and Stockholm, have been shown to reduce transportation by single occupancy vehicles and lower carbon emissions (Newberry 2005).
- Carbon/energy/fuel taxes with the main motivation to mitigate climate change also reduce environmental risks and threats to ecosystems (Ekins 1999).
- Eco-VAT. In Brazil, an ecological value added tax is paid to municipal governments (Farley and Costanza 2010).

However, while these targeted fees and taxes, and VAT more generally, dampen consumption, very few direct consumption taxes have been designed specifically in order to preserve nature and NCP. Taxes can be combined with other economic instruments for these ends; for example, revenues from taxes may be used to finance other biodiversity-conserving activities, like protected areas (Farley and Costanza 2010; Raes *et al.*, 2016). As no global assessment of the effectiveness of these kinds of taxes is found in the literature, the evidence remains inconclusive (Hogg *et al.*, 2014). More empirical work on the experimental use of different taxation schemes and their environmental outcomes is recommended.

Local and regional governments across the world are also investing in a wide range of programs to encourage more resource-light consumption including elements of sufficiency such as hosting repair cafes, materials exchanges/swaps, and innovating 'collaborative consumption' events like tool lending libraries. Authorities have also indirect influences on consumption patterns and levels: public transport planning can enhance the accessibility without car use, with positive environmental and quality of life outcomes. Additionally, in most countries, public procurement is the single largest purchaser of goods and services. This gives public authorities from the local to international level the opportunity to strengthen sustainable suppliers and nudge others towards greening their offers, by stimulating the demand for energy saving buildings, recycled products or organic food, reducing the consumption of materials, energy and land and thus mitigating several direct and indirect drivers of nature deterioration (Brammer & Walker 2011; Lutz 2009).

Corporate action reducing consumption: Corporations and industry associations have responded to consumer demand through sustainable sourcing practices and consumer awareness campaigns in the interest of both resource protection and building brand loyalty. However, Williamson *et al.* (2006) found that such voluntary approaches will not alter the behaviour of manufacturing enterprises significantly unless they have a positive effect on the bottom line, e.g. by reducing resource or labor cost, ensuring employee morale (Jacobsen & Dulsrud 2007) or avoiding regulation by pre-empting measures (Marsden & Flynn 2000). The research on such Corporate Social Responsibility (CSR) programs tends to conceptual rather than empirical, except for some labelling and certification programs (Carlson *et al.*, 2018). See Supplementary Materials 6.6.1 for a detailed discussion on addressing overconsumption.

6.4.3 Reducing unsustainable production

Several studies have shown that production systems focused on economic growth correlate with increasing environmental impacts, both on micro/household and on macro/cross-national levels (Hayden & Shandra 2009; Rosnick & Weisbrot 2007; EEA 2014; Ward *et al.*, 2016). Policy options include the setting of resource caps and taxes, transitioning to a circular economy, corporate social responsibility, and using life cycle analysis as a policy support tool.

Resource caps and taxes: Resource caps and taxes are a way to limit the volume of resources used or produced in production processes. Examples with positive environmental effects include water extraction charges or energy sector charges (McDonald *et al.*, 2012), e.g., car fleet gasoline consumption limits as an obligation to manufacturers and public procurement. Caps and taxes support transformative change as reducing supply modifies the competition rules in a market economy, requiring companies to redesign products and business models by taking resource limitations (and implicitly biodiversity aspects) into account alongside economic considerations throughout the supply chain (Ayres 1989). A large number of studies have shown that avoidance costs tend to be lower than damage and repair costs (Aslaksen *et al.*, 2013; Gee *et al.*, 2013; Simberloff 2014, EEA 2017).

As one example, carbon pricing is currently in discussion as a possible way to spur development of non-fossil fuel energy sources and reduce carbon emissions (Essl & Mauerhofer 2018); a recent study found that while the potential to raise revenue from carbon pricing is highly variable depending on country's emission intensity and economic activity, many low income countries could finance much of their needs to implement the SDG with a carbon pricing scheme starting at $40/ton (Franks *et al.*, 2018). To avoid disproportionate negative effects on producers and resulting rises in prices, resource caps and taxes can be complemented with compensatory measures, such as carbon dividends and subsidies to low income energy users.

Transitioning to a circular economy: The major aim of the Circular Economy (CE) is to decouple economic growth and the deterioration of the environment (Ghisellini *et al.*, 2016), suggesting that economic prosperity and improved environmental quality can be achieved together at the same time (Kirchherr *et al.*, 2017) through technological, economic and social innovations (Jesus & Mendonça 2017). There are many competing definitions about what the circular economy is and how far it can be implemented at the micro (e.g. company, consumer), meso (e.g. industrial park) or the macro (regional, national, global) level (Kirchherr *et al.*, 2017). According to a frequently cited definition, CE is "an industrial system that is restorative or regenerative by intention and design. It replaces the ‹end-of-life› concept with restoration, shifts towards the use of renewable energy, eliminates the use of toxic chemicals, which impair reuse, and aims for the elimination of waste through the superior design of materials, products, systems, and within this, business models." (Ellen MacArthur Foundation 2013: p7). Most discussions about CE recognize that it may not be possible to make the economy fully circular. For example, **Figure 6.7** offers a representation of the CE that allows for raw materials input and residual waste outputs.

CE is promoted in various countries worldwide (for examples, see Supplementary Materials 6.6.2). Nevertheless, consensus is still lacking on how far the global economy is progressing towards a CE. Cooper *et al.* (2017) estimated that potential savings of energy used for economic activities worldwide could reach 6-11%, while Haas *et al.* (2015) carried out a material flows analysis on data from 2005 and estimated that the recycling within the economy as share of processed material reached 6%

Figure 6 7 **Depiction of the circular economy.**

Source: https://www.europarl.europa.eu/ireland/en/news-press/circular-economy-meps-call-for-“systemic-change”-to-address-resource-scarcity.

globally and 13% in the EU. Reasons for these relatively low numbers are thought to be the large proportion of non-recyclable fossil fuel and biomass material throughput (Haas *et al.*, 2015), and the accelerating production due to the rebound effect (Zink & Geyer 2017). Other factors include policy and enforcement failures, consumer preferences, costs, and infrastructure deficits (for details, see Supplementary Materials 6.6.2).

Corporate social responsibility (CSR): CSR initiatives are voluntary efforts by companies to address social and environmental concerns arising from business activities (Robinson 2011; European Commission 2011, Dyllick & Hockerts 2002; Baumgartner 2014; O'Connor & Spangenberg 2008). CSR is used by sectors that are directly affected by the degradation of local ecosystems and habitat loss (e.g. fisheries, agriculture, forestry, tourism) (Boiral & Heras-Saizarbitoria 2017; Hastings & Botsford 2003; Pickering & Hill 2007) as well as sectors that are indirectly affected through their globalized supply chains (Robinson 2011). The idea of CSR is that companies have the potential and responsibility to make a substantial contribution to arresting declines in biodiversity and ecosystems services (Armsworth 2010; Lambooy 2011; Athanas 2005; 'Biodiversity in Good Company' Initiative https://www.business-and-biodiversity.de/en/about-us/). The ultimate role of companies should be to identify, to be transparent and accountable for their impacts (ISO 26000) (ISO 2010), and to develop strategies to reduce negative and to maximize positive impacts. However, since the inception of the CBD in 1992, little progress has been achieved in terms of involving the business community in protecting biological diversity worldwide (Overbeek *et al.*, 2013). For instance, most of the Fortune 500 companies do not systematically record their activities regarding biodiversity and ecosystems service management (Bhattacharya, 2013); a recent study found only 5 companies in the Fortune 100 had specific and measurable commitments to biodiversity (Addison *et al.*, 2018). However, research suggests that business profits and good condition of biodiversity are often correlated (Tilman *et al.*, 2006; Worm & Barbier

2006; Bishop *et al.*, 2008; Lambooy 2011) (see also Supplementary Materials 6.6.2).

Using life cycle analysis as a policy support tool: Life cycle assessment (LCA) offers a method for quantitatively assessing and evaluating the inputs, outputs, and potential environmental impacts of a product system throughout its life cycle (ISO 2006a). It is widely applied by companies (Frankl & Rubik 2000; Clift & Druckman 2015) to inform consumers (Del Borghi 2013) and for public policy making (Owsianiak *et al.*, 2018). However, the inclusion of biodiversity in LCA has been limited to specific species or has related factors such as climate change or land use (Verones *et al.*, 2017; Goedkeep *et al.*, 2013; deBaan *et al.*, 2013; Schenk 2001; Penman *et al.*, 2010; Curran *et al.*, 2011; Koellner *et al.*, 2013; Souza *et al.*, 2015; Winter *et al.*, 2017; Chaundhary *et al.*, 2015; see Supplementary Materials 6.6.2). Several authors have discussed options to incorporate ecosystem services into LCA (Zhang *et al.*, 2010 a, b; Bakshi & Small 2011; Koellner & Geyer 2011; Cao *et al.*, 2015; Othoniel *et al.*, 2016; Blanco *et al.*, 2017; Bruel *et al.*, 2016) but so far with little progress. LCA approaches have a number of limitations, as they present many choices and assumptions, are complex and require sufficient and standardized data, provide a snapshot at a specific point in time which may be outdated by innovation or modified supply chains by the time the data is used, and focus on reducing the impacts per unit of consumption, not on reducing consumption levels themselves (Pré Consultants 2006; Finkbeiner 2014; Galatola & Pant 2014).

6.4.4 Reforming trade regimes to address disparities and distortions

Key global commodities with negative impacts on nature are among the major items traded internationally and subject to rules through the WTO and other regional and bilateral trade deals. There is growing evidence that these trading rules often encourage overproduction or unsustainable production, and that future markets can create pressures for expansion of production in unsustainable ways (Pace & Gephart 2017; Bruckner *et al.*, 2015). While challenging, it is increasingly acknowledged that reforming trade systems and financial markets is essential to controlling the impact of global economic drivers on nature.

Reforming the trade system: There are general concerns that trade liberalization contains considerable risks for nature and the environment. For example, tensions have been identified between WTO regulations, particularly the General Agreement on Tariffs and Trade (GATT) and environmental concerns. Documented cases focus on efforts to ban tuna from fisheries operations and nations that do not implement dolphin conservation measures (Waincymer 1998) or, similarly, to ban shrimp from fisheries operations and nations that do not implement turtle conservation measures (Benson 2003). Other examples include domestic support for multifunctional agriculture (see also 6.3.2) (Dibsen *et al.*, 2009; Hasund 2013, Potter & Burney 2002; Potter & Tilzey 2007). Tensions have also been identified between the GATT and biosecurity issues related to preventing diseases and invasive species from entering (Maye *et al.*, 2012).

A different issue identified in literature is related to the WTO Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) (Brand & Görg 2003). While the potential of WTO and other free trade agreements and WTO regulations to contribute to conservation and sustainability is criticized (Waincymer 1998; Brand & Görg 2003), some suggest that the inclusion of environmental provisions in TRIPS can prevent negative environmental impacts and even promote conservation and good environmental practices (Neumayer 2000; Ivanova & Angeles 2006). Opportunities within WTO have been identified in the Technical Barriers to Trade (TBT) agreements and in Preferential Trade Agreements (Charnovitz 2007). Also, the Geographical Indications (GI), part of TRIPS, can provide opportunities for conservation and sustainability, but only if nature and biodiversity friendly practices are embedded in the GI specification (Garcia *et al.*, 2007).

While other regional or bilateral free trade agreements such as NAFTA include environmental provisions, these have mostly been implemented in a narrow way and have not resulted in significantly raised levels of environmental protection (Sanchez 2002). At the global level, WTO has started to discuss environmental provisions as part of the Doha negotiations since 2001, but negotiations were not successful and ended in 2016. Since then, bilateral trade agreements have increased in importance, as have the intensification of 'trade wars'. The consequences of this situation for international cooperation, as well as for nature, its contributions and the quality of life are yet to be determined.

Reforming derivative and futures markets: The increasing trade in futures and derivatives over the past decade have been associated with outcomes that affect biodiversity. Futures and comparable financial products such as derivatives are essentially contracts between buyers and sellers of commodities that stipulate volumes, price and delivery date (Pollard *et al.*, 2008). Derivatives and futures turn variability into a credit risk that can be hedged against, traded, and speculated on, and signal the ongoing commodification of new forms of nature (Smith 2007; Cooper 2010). For example, climate and weather derivatives have emerged, seen as a flexible and cost-effective way for companies to reduce risk and become more creditworthy (Pryke 2007; Cooper 2010). While futures and derivatives contracts can offer potential income stability and protection against risks, they are also an opportunity for speculation and hedging on price movements which can lead to turbulence and price volatility (Cooper 2010). This means that, when unregulated, these markets can pose a potential threat to sustainability and contribute to social crises (Heltberg *et al.*, 2012).

In the United States, home to the largest commodity futures markets, financial regulations designed to prevent excessive levels of speculation by financial investors were in place for much of the 20th century. These rules included reporting requirements as well as 'position limits' that restricted the number of commodity futures contracts purely financial investors (also referred to as 'non-commercial operators') could hold at any given time. Over the course of the 1980s to early 2000s, these regulations were gradually relaxed (Clapp & Helleiner 2012). Following the deregulation of the US futures markets, speculative investment in agricultural commodities increased from US$ 65 billion in 2006 to US$ 126 billion in 2011 (Worthy 2011). It has been suggested that this contributed in part to the 2007-2008 food crisis, as a number of observers noted that food prices were rising more quickly and sharply than was warranted by the underlying fundamentals of supply and demand for those crops at the time (e.g., FAO 2008). Analysts identified speculative financial investment, including commodity index products marketed to large institutional investors, as a potential factor in driving up food prices (Masters 2008; Ghosh 2010) with severe impacts on the quality of life in many countries (Ivanic & Martin 2008; Bellemare 2015). Although there is debate over the extent to which financial speculators were responsible (see, for example, Sanders & Irwin 2010), several international organizations have noted that financial speculation in agricultural commodity markets can make food price trends more volatile (BIS 2011; UNCTAD 2011). Higher and more volatile food prices matter for biodiversity because when food prices rise, investment in agricultural production also typically rises, influencing land-use trends. At the height of food price volatility in the 2008-2013 period, there was a rush to increase production, especially of cereal crops such as wheat, maize and rice, as well as oil crops such as soy (FAO 2017).

As commodity exchanges around the world, including in developing countries, develop to include more sophisticated financial and investment products, it is important for them to consider adopting regulations that seek to limit excessive financial speculation on those markets that can affect biodiversity outcomes (FAO *et al.*, 2011): for example, by putting limits on the number of contracts per trader in each market (Ghosh *et al.*, 2012) and by enhancing market transparency (Clapp 2009; Minot 2014). In the wake of the 2008 financial crisis, governments around the world sought to tighten regulations on commodities futures markets with a view to reining in speculative financial investments that could affect prices and destabilize markets (Helleiner 2018). In the United States, the Dodd-Frank Wall Street Reform and Consumer Protection Act authorized the adoption of new rules to strengthen the position limits and reporting requirements to restrain excessive speculation. However, the substance of these rules has been weakened and their implementation has been delayed following extensive lobbying and court challenges from the financial industry. The European Union also developed more stringent regulations known as Mifid II, but these rules were also weakened in the face of the financial industry. It is unclear whether the new regulations in the US and EU, once fully implemented, will achieve their intended effect, and their subsequent impact on agricultural outcomes that affect biodiversity.

6.4.5 New models for a sustainable economy

In recent decades, many have questioned the economic growth paradigm and its compatibility not only with environmental sustainability but also achieving a good quality of life for all. The challenges of climate change and biodiversity loss, in particular, underline that the scale of economic activity has already pushed society out of the safe operating space of the planet (Rockström *et al.*, 2009; IPCC 2018). By detaching mainstream paradigms of unending economic growth from economic and social relations, alternative ways of understanding human and societal well-being have been proposed (Costanza *et al.*, 2014; Cattaneo 2014; O'Neill 2012). A central idea in these approaches is to decouple growth of the economy and enhancement of human well-being from resource use and extraction. The most prominent models are the Green Economy (also called Green Growth or Inclusive Green Growth, promoted by the OECD, UNEP and EU), which builds upon earlier discussion on ecological modernization (Mol & Spaargaren 2000), and the model of (physical) Degrowth leading to a steady state economy (Daly 1974; Denaria *et al.*, 2013).

The core assumption of the Green Economy model is that increasing economic activity as well as the generation of income and jobs can be achieved without becoming unsustainable. Key strategies in this endeavor include increasing the efficiency of resource use by means of technological and social innovations (York & Rosa 2003) and transitioning towards more sustainable patterns of consumption (UNEP 2002). Other discussions highlight the possibilities of substituting natural capital for human capital and human made capital (Pearce *et al.*, 1989; Pearce & Barbier 2000), while protecting a critical level of natural capital (Deutsch *et al.*, 2003; Ekins 2003).

The toolbox used in green economy policies typically includes a mix of regulatory (laws, voluntary agreements), economic or market based (green taxes, credits, certification, subsidies, offsetting, PES, circular economy) and informational instruments (labeling, consumer campaigns), with an emphasis on the latter two. On the consumption side, Green Economy strategies call for (voluntary) changes in consumption patterns towards the growth in production and consumption of non-material or non-resource intensive goods and services. There are however strong criticisms to this Green Economy concept arguing that the suggested measures may indeed be indispensable, but not sufficient in the long term and that more fundamental change is necessary (Victor 2008; Jackson 2009).

Degrowth, including the older idea of a steady state economy (Daly 1974), contests the necessity of economic growth as a condition of human well-being and good quality of life. Foremost amongst these is that for an economy to remain within ecological bounds, it must possess a constant stock of physical capital at a level that can be maintained by material flows remaining within the regenerative capacity of the ecosystem (Daly 1974). Only if economic output could be decoupled from resource use, growth in Gross Domestic Product (GDP) would be consistent with sustainability. Models of degrowth go beyond the physical steady state and advocate "an equitable downscaling of production and consumption that increases human well-being and enhances ecological conditions at the local and global levels, in the short and long-terms" (Schneider *et al.*, 2010:512). This implies reduced growth in the physical part of the economy and as a result in the monetary or financial side (Spangenberg 2010). On the consumption side, degrowth goes beyond greener consumption patterns by advocating for reduced consumption levels overall.

Strategies for degrowth include limits on resource extraction, new social security guarantees and work-sharing (reduced work hours); universal basic income and income caps (see Supplementary Materials 6.6.3); consumption sufficiency, and resource taxes with affordability safeguards; redistribution of wealth, support of innovative models of "local living"; commercial and commerce free zones; new forms of money; high reserve requirements for banks; ethical banking; green investments; cooperative property and cooperative firms (Eckersley Ro 2006; Jackson 2009; Korten 2008; Latouche 2009; Spangenberg 2010; Klitgaard & Krall 2012; Heikkurinen 2016; Samerski 2016). Already existing practices that adopt these models or parts include eco-communities and villages, cooperatives, community currencies, time banking or urban gardening (e.g., Cattaneo & Gavaldà 2010; Nierling 2012; 2010; Dittmer 2013; Xue 2014; LeBlanc 2017; McGuirk 2017). In a degrowth strategy, these practices are integrated with selected instruments from the green economy toolbox, like green taxes or consumer campaigns (Kallis *et al.*, 2012; Rigon 2017), but not others such as biodiversity banking due to reservations against the commodification of nature (Gómez-Baggethun & Ruiz-Pérez 2011).

Evidence of the effectiveness of alternative models of the economy, including associated strategies and practices, is inconclusive. Yet, existing evidence shows that current strategies and practices have not accomplished a decoupling of economic growth from energy and materials consumption over an extended time span (chapter 2). Without an adjustment of orientations and priorities, including an effective instrumentation of such policies, a sustainable economy is not going to be achieved. These alternative models and associated strategies and practices offer opportunities to promote nature and its contributions, recognize value pluralism (Pascual *et al.*, 2017), and enhance inclusiveness as recognized in the SDG. An example of such a value pluralist approach is the concept of Good Living ("Buen Vivir"), which means material, social and spiritual well-being of people who live not at the cost of others or nature (Brand *et al.*, 2017; Beling *et al.*, 2018). This concept of Good Living has been adopted in the Bolivian constitution, calling for recognition of the rights of nature and holistic understanding (IPBES 2016; Pacheco 2014a, b), albeit with limited impact on the country's neo-extractivist policy (Beling *et al.*, 2018). Other examples include the broad discussion on the transition to an "ecological civilization" in China (Yan & Spangenberg 2018).

Since the GDP does not capture the state of the environment, biodiversity nature and its contributions, and is not a measure of welfare in itself, the discussion of alternative models of the economy has extended to the development of alternative measures to represent human well-being and good quality of life (see chapter 2). Some, like the Index of Sustainable Economic Welfare (ISEW) (Daly & Cobb 1989) and the Genuine Progress Indicator (GPI) (Cobb *et al.*, 1995), are based on GDP calculation; subtracting the "bads" like environmental degradation and biodiversity loss in monetary terms and adding the "goods" not included in the GDP such as the value of unpaid work. A comprehensive set of indicators for short and longer-term development has been suggested by the Stiglitz-Sen-Fitoussi Commission set up by the French government (Stiglitz *et al.*, 2010). Another prominent measure is the Gross National Happiness Index, introduced by the Bhutanese Government. This measure focuses on equitable social development, cultural preservation and conservation of the environment (Verma *et al.*, 2017). Recently, local, regional and national governments, including different States in the US (see Talberth & Weisdorf 2017 for an overview), and Belgium (Bleys 2013) have shown interest in these measures.

Further innovations have been proposed in accounting systems to incorporate environment and ecosystems. To this end, UN Statistics extended the international statistical system by satellite accounts of physical flows and environmental goods, and in its latest version the value of ecosystems and their services (https://seea.un.org/). This includes amongst others Material Flow Accounting (MFA) and Material and Energy Flow Accounting (MEFA) (Bringezu *et al.*, 1997; Haberl *et al.*, 2004) and Natural Capital (NC) assessment and accounting (Natural Capital Coalition 2017). There is a wide variety in methods and approaches. Some of these focus on only one ecosystem service or form of capital (for example carbon), some use formal accounting methods and involve monetization, and again others use non-monetary units to quantify and express environmental stocks and flows (Day 2013; Faccoli *et al.*, 2016; Bateman *et al.*, 2011; Donnely *et al.*, 2016; Agrawala *et al.*, 2014; Robèrt 2002; Schmidt-Bleek 2008; Spangenberg *et al.*, 1998; Dittrich *et al.*, 2012; Ulgiati *et al.*, 2011, Ayres *et al.*, 1996; Steen-Olsen *et al.*, 2012; Giampietro *et al.*, 2014; Lomas & Giampietro 2017; ten Brink 2012; UNU-UHDP and IHDP 2014) (see Supplementary Materials 6.6.3).

There is as yet no evidence of the effectiveness of the use of environmental accounting approaches. As an information instrument, its effectiveness is based on the premise that more information will result in better decision-making (Guerry *et al.*, 2015; Mace *et al.*, 2015) – a premise that is largely unsupported (Caceres *et al.*, 2016; Turnhout *et al.*, 2013; Wesselink *et al.*, 2013). Yet, as has been shown for other information tools such as models or indicators (Turnhout *et al.*, 2007; Van Egmond & Zeiss 2010; see Section 6.2.2), environmental accounting may be helpful as a tool for the facilitation of dialogue on the diverse values of nature and biodiversity. However, in order to enable this role, it is important that it uses a broad perspective that includes non-economic values and that it employs a participatory approach so that relevant stakeholders can contribute to the definition and identification of indicators for nature, ecosystem services, environmental assets, and natural capital (Turnhout *et al.*, 2007; Raymond *et al.*, 2009).

6.4.6 Conclusions

The existing economic system of capital-intensive exploitation of nature, extensive international trade and their telecouplings, and wide-ranging inequality between countries and between peoples within countries, is not a system that is natural or to which there is no alternative. To the contrary, such an economic system has evolved over time due to human interventions, institutions, policy choices and options, and as such, can be transformed just as it was created. The problem is often one of both recognizing the scope of the problem through sharing information, implementing more inclusive and realistic economic accounting, as well as tackling reforms to the system through gradual incremental changes like changing consumer behaviour, incentivizing different economic pathways, reducing production impacts, and reforming trade, subsidies and markets or various kinds. More transformative options like creating circular economies, moving to degrowth and steady-state economic paradigms, tackling inequality, and revamping the way we finance and prioritize conservation of nature and biodiversity will require concerted efforts from a range of decision makers, with national governments, private corporations and international institutions leading the way. Designing such an integrated world economy that values nature and its contributions in pluralistic ways, recognizes their long-term importance to human quality of life, and rightfully prioritizes them as public goods above private profit is a long-term vision that will require innovative, imaginative and adaptive ways to transform our current economic and governance systems.

ANNEXES

ANNEX I
Glossary

A

Abundance
The size of a population of a particular life form (IPBES, 2016).

Abyssal plain
An extensive level area of the deep ocean floor typically situated between the foot of the continental rise or mid-ocean ridge and an oceanic trench and covered with fine sediments.

Access and benefit sharing (ABS)
Access and benefit-sharing (ABS) refers to the way in which genetic resources may be accessed, and how the benefits that result from their use are shared between the people or countries using the resources (users) and the people or countries that provide them (providers). In some cases, this also includes valuable traditional knowledge associated with genetic resources that comes from Indigenous Peoples and Local Communities. The benefits to be shared can be monetary, such as sharing royalties when the resources are used to create a commercial product, or non-monetary, such as the development of research skills and knowledge (Convention on Biological Diversity, 2002, 2010a, 2010b).

Acidification
Ongoing decrease in pH away from neutral value of 7. Often used in reference to oceans, freshwater or soils, as a result of uptake of carbon dioxide from the atmosphere (see 'Ocean acidification' for a specific definition).

Adaptability (part of resilience)
The capacity to adjust responses to changing external drivers and internal processes, and thereby channel development along the preferred trajectory in what is called a stability domain (Walker *et al.*, 2004).

Adaptive capacity
The general ability of institutions, systems, and individuals to adjust to potential damage, to take advantage of opportunities, or to cope with the consequences (Millenium Ecosystem Assessment, 2005).

Adaptive management
A systematic process for continually improving management policies and practices by learning from the outcomes of previously employed policies and practices. In active adaptive management, management is treated as a deliberate experiment for purposes of learning (Millenium Ecosystem Assessment, 2005).

Adaptive radiation
The evolution of a number of divergent species from a common ancestor, each species becoming adapted to occupy a different ecological niche (Lawrence, 2005).

Aerosol
A collection of solid or liquid particles suspended in a gas. They include dust, smoke, mist, fog, haze, clouds, and smog (Hinds, 1999).

Afforestation
Planting of new forests on lands that historically have not contained forests (IPCC, 2014a).

Agricultural extensification
The process of low and/or decreasing the use of capital and inputs (e.g., fertilisers, pesticides, machinery, labour) relative to land area (EUROSTAT, 2018a).

Agricultural intensification
The process of increasing the use of capital, labour, and inputs (e.g., fertilisers, pesticides, machinery) relative to land area, to increase agriculture productivity (EUROSTAT, 2018b).

Agrobiodiversity
Agricultural biodiversity includes all components of biological diversity of relevance to food and agriculture, and all components of biological diversity that constitute the agricultural ecosystems, also named agro-ecosystems: the variety and variability of animals, plants and micro-organisms, at the genetic, species and ecosystem levels, which are necessary to sustain key functions of the agro-ecosystem, its structure and processes (Convention on Biological Diversity, 2000).

Agroecology
The science and practice of applying ecological concepts, principles and knowledge (i.e., the interactions of, and explanations for, the diversity, abundance and activities of organisms) to the study, design and management of sustainable agroecosystems. It includes the roles of human beings as a central organism in agroecology by way of social and economic processes in farming systems. Agroecology examines the roles and interactions among all relevant biophysical, technical and socioeconomic as well as sociopolitical components of farming systems and their surrounding landscapes.

Agroecosystem
An ecosystem, dominated by agriculture, containing assets and functions such as biodiversity, ecological succession and food webs. An agroecosystem is not restricted to the immediate site of agricultural activity (e.g., the farm), but rather includes the region that is impacted by this activity, usually by changes to the complexity of species assemblages and energy flows, as well as to the net nutrient balance.

Agroforestry
Agroforestry is a collective name for land-use systems and technologies where woody perennials (trees, shrubs, palms, bamboos, etc.) are deliberately used on the same land-management units as other agricultural crops and animals, in some form of spatial arrangement or temporal sequence (Choudhury & Jansen, 1999). For spatial quantification purposes, agroforestry has been defined on the basis of the percentage of tree cover on agricultural land, such as above 10% in Zomer *et al.* (2009).

Albedo
The fraction of solar radiation reflected by a surface or object, often expressed as a percentage (IPCC, 2014a).

Alpha diversity
The diversity of species within a particular area or ecosystem, expressed by the number of species (species richness) present there (Park, 2007).

Animism
A nature-culture ontology that is defined by the fact that humans acknowledge that non-humans have a different physicality or external appearance but that non-humans have an inner self that is similar to humans, which allows exchanges and relationships that may be conflictual or reciprocal.

Anoxic event
Extreme coastal hypoxic conditions (dissolved oxygen <0.5mL per liter), leading to "dead zones" with mass mortality of benthic fauna (Altieri *et al.*, 2017; Diaz & Rosenberg, 2008).

Anthrome
A shortened form for 'anthropogenic biome', also known as 'human biome'. Describes the contemporary, human-altered form of biomes. Transformation to an anthrome occurs where people capture one or more nature's contributions to people into anthropogenic pathways to a high degree. The four IPBES anthromes are broader and more aggregated than many formally described anthromes. Since anthromes are transformed parts of a biome, the pre-transformation extent of the biome may be relevant for analysis (Alessa & Chapin III, 2008; Ellis & Ramankutty, 2008).

Anthropocene
A proposed term for the present time interval, which recognizes humanity's profound imprint on and role in the functioning of the Earth system. Since it was first proposed in 2000 (Crutzen, 2002; Crutzen & Stoermer, 2000), the term has evolved in breadth and diversely, now ranging from a proposed definition of a new geological epoch, a widely-used metaphor for global change, a novel analytical framework, a meme about the relationship of society to nature, and the framing for new and contested cultural narratives. Different starting periods have been proposed for the geological definition of the Anthropocene, including early agriculture and domestication, colonial species exchange, the onset of the industrial revolution, nuclear bomb deployment in 1945, and the post-WWII period characterized by the great acceleration of global changes and the spread of techno-fossils (Brondizio *et al.*, 2016). A proposal to formalize the 'Anthropocene' as a defined geological unit within the Geological Time Scale remains under discussion by the 'Anthropocene' Working Group for consideration by the International Commission on Stratigraphy (IUGS, 2018).

Anthropocentric
Anthropocentric qualifies an action or a perception of a given situation that is interpreted by humans or consider humans as the main focus. Nature's contributions to people are fundamentally anthropocentric.

Anthropogenic assets
Built-up infrastructure, health facilities, or knowledge - including indigenous and local knowledge systems and technical or scientific knowledge - as well as formal and non-formal education, technology (both physical objects and procedures), and financial assets. Anthropogenic assets have been highlighted to emphasize that a good quality of life is achieved by a co-production of benefits between nature and people.

Anthropogenic biome
See 'Anthrome'.

Anthropogenic landscapes
Areas of Earth's terrestrial surface where direct human alteration of ecological patterns and processes is significant, ongoing, and directed toward servicing the needs of human populations for food, shelter and other resources and services including recreation and aesthetic needs (Ellis *et al.*, 2006).

Aquaculture
The farming of aquatic organisms, including fish, mollusks, crustaceans and aquatic plants, in both inland and coastal areas, and involving some form of intervention in the rearing process to enhance production, such as regular stocking, feeding, protection from predators, etc. Farming also implies individual or corporate ownership of the stock being cultivated (FAO, 1997).

Archetype
In the context of scenarios, an over-arching scenario that embodies common characteristics of a number of more specific scenarios.

Article 8(j) of the CBD
Article 8(j) states that each contracting Party of the Convention on Biological Diversity shall, as far as possible and as appropriate, subject to national legislation, respect, preserve and maintain knowledge, innovations and practices of indigenous and local communities embodying traditional lifestyles relevant for the conservation and sustainable use of biological diversity and promote their wider application with the approval and involvement of the holders of such knowledge, innovations and practices and encourage the equitable sharing of the benefits arising from the utilization of such knowledge innovations and practices (Convention on Biological Diversity, 1992).

Average genetic variation (heterozygosity)
The condition of having two different alleles at a gene locus (Allendorf, 2014).

Avoided deforestation in conjunction with afforestation and reforestation (ADAFF)
Land-based climate change mitigation strategy based on maintaining and expanding global forest area, and thus the carbon uptake of forest ecosystems in biomass and soil (Krause *et al.*, 2017).

B

Basal area
Area occupied by the cross-section of tree trunks and stems at base height (130cm from the ground). It is used to characterize different variables in forest ecology and management, e.g., forest structure, productivity and growth rate (Faber-Langendoen & Gentry, 1991).

Benefit sharing
Distribution of benefits between stakeholders.

Benthic
Occurring at the bottom of a body of water; related to benthos (NOAA, 2018b).

Biocentric worldview
Ethical perspective holding that all life (including humans, fauna, flora and domestic animals) deserves equal moral consideration or has equal moral standing (DesJardins, 2013). It contrasts with worldviews characterized as anthropocentric, which places humans at the center.

Biochemical oxygen demand (BOD)
A measure of the amount of oxygen required or consumed for the microbiological decomposition (oxidation) of organic material in water. The purpose of this indicator is to assess the quality of water available to consumers in localities or communities for basic and commercial needs. It is also one of a group of indicators of ecosystem health (United Nations, 2007).

Biocultural approaches to conservation / biocultural conservation
Conservation actions made in the service of sustaining the biophysical and sociocultural components of dynamic, interacting, and interdependent social–ecological systems (Gavin *et al.*, 2015).

Biocultural diversity
Biocultural diversity is considered as biological and cultural diversity and the links between them (CBD, 2018b).

Biodiversity
The variability among living organisms from all sources including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are a part. This includes variation in genetic, phenotypic, phylogenetic, and functional attributes, as well as changes in abundance and distribution over time and space within and among species, biological communities and ecosystems.

Biodiversity conservation
The management of human interactions with genes, species, and ecosystems so as to provide the maximum benefit to the present generation while maintaining their potential to meet the needs and aspirations of future generations; encompasses elements of saving, studying, and using biodiversity (WRI *et al.*, 1992).

Biodiversity hotspot
A generic term for an area high in such biodiversity attributes as species richness or endemism. It may also be used in assessments as a precise term applied to geographic areas defined according to two criteria (Myers *et al.*, 2000): (i) containing at least 1,500 species of the world's 300,000 vascular plant species as endemics, and (ii) being under threat, in having lost 70 % of its primary vegetation.

Biodiversity Intactness Index
An indicator of the average abundance of a large and diverse set of organisms in a given geographical area, relative to their reference populations (Scholes & Biggs, 2005).

Biodiversity offset
Measurable conservation outcomes resulting from actions designed to compensate for significant residual adverse biodiversity impacts arising from development plans or projects after appropriate prevention and mitigation measures have been taken. The goal of biodiversity offsets is to achieve no net loss and preferably a net gain of biodiversity on the ground with respect to species composition, habitat structure, ecosystem function and people's use and cultural values associated with biodiversity (UNDP, 2016a).

Bioenergy
Energy generated by combusting solid, liquid or gas fuels made from biomass feedstocks, which may or may not have undergone some form of conversion process (Committee on Climate Change, 2011).

Bioenergy in combination with carbon capture and storage (BECCS)
Land-based climate change mitigation strategy involving the planting of bioenergy crops or trees, which are burned in power stations or converted to biofuels, and the released CO_2 being captured for long-term underground storage in geological reservoirs (Krause *et al.*, 2017).

Bioethanol
See 'Biofuel'.

Biofuel
Liquid, solid, or gaseous fuel produced by conversion of biomass. Examples include bioethanol from sugar cane or corn, charcoal or woodchips, and biogas from anaerobic decomposition of wastes (OECD, 2002).

Biogas
See 'Biofuel'.

Biogenic volatile organic compounds (BVOC)
Compounds that include organic atmospheric trace gases other than carbon dioxide and carbon monoxide; isoprenoids (isoprene and monoterpenes) are among the most prominent BVOC emitted (Kesselmeier & Staudt, 1999).

Biogeochemical cycles
Biogeochemical cycles involve the fluxes of chemical elements among different parts of the Earth: from living to non-living, from atmosphere to land to sea, and from soils to plants (Galloway *et al.*, 2014).

Biological conservation
See also 'Biodiversity conservation'. Application of science to conservation problems addressing the biology of species, communities and the ecosystem that are perturbed either directly or indirectly by human or other agents. Its goal is to provide principles and tools for preserving biological diversity. The branch of biology that deals with threats to biodiversity and with preserving the biologic and genetic diversity of animals and plants (Soulé, 1985).

Biological Oxygen Demand (BOD)
See 'Biochemical Oxygen Demand (BOD)'.

Biological pump
The fixation of carbon at the oceans' surface by photosynthesizing organisms and subsequent sinking of a sizable fraction (15–20%) of total productivity creates a strong vertical transport that dominates the distribution of carbon, nutrients, and oxygen in the ocean, known as the 'biological pump' (Ridgwell, 2011).

Biological resources
Biological resources includes genetic resources, organisms or parts thereof, populations, or any other biotic component of ecosystems with actual or potential use or value for humanity (Convention on Biological Diversity, 1992).

Biomass (ecology)
The mass of non-fossilized and biodegradable organic material originating from plants, animals and micro-organisms in a given area or volume.

Biomass (for production)
Biological material that can be used as fuel or for industrial production. Includes solid biomass such as wood, plant and animal products, gases and liquids derived from biomass, industrial waste and municipal waste (US Energy Information Administration, 2018).

Biome
A set of naturally occurring communities of plants and animals occupying an environmental and/or climatic domain, defined on a global scale. IPBES biomes (e.g., tropical and subtropical forests, shelf ecosystems, inland waters) are broader and more aggregated than many purely biological classification systems. Where biomes are transformed into anthromes, the pre-impact range of the biome may still be relevant for analysis. 'Natural biome' may be used to distinguish from 'anthropogenic biome' or 'anthrome'.

Bioprospecting
The purposeful evaluation of plant and animal biological material in search of valuable new products (Artuso, 2002).

Biosphere
The part of the Earth system comprising all ecosystems and living organisms, in the atmosphere, on land (terrestrial biosphere) or in the oceans (marine biosphere), including derived dead organic matter, such as litter, soil organic matter and oceanic detritus (IPCC, 2014a).

Biotechnology
Any technological application that uses biological systems, living organisms, or derivatives thereof, to make or modify products or processes for specific use (Convention on Biological Diversity, 1992).

Blue carbon
The carbon stored in marine and coastal ecosystems (Howard *et al.*, 2014).

Bottom-up control of the food web
A mode of control of trophic interactions by resources, in which organisms on each trophic level are food limited, as opposed to a top-down control (by predators), in which organisms at the top of food chains are food limited, and at successive lower levels, they are alternately predator, then food limited (Power, 1992).

Buen vivir
There is no single definition of Buen Vivir. Generally, it refers to an alternative to economic development-centered approaches, generally defined as forming part of the Andean indigenous cosmology, based on the belief that true wellbeing is only possible as part of a community in a broad sense, including people, nature and the Earth, linked by mutual responsibilities and obligations, and that the wellbeing of the community is above that of the individual.

Buffer (ecology)
A natural or anthropogenic feature which separates land uses.

Buffer zones (protected areas)
Areas between core protected areas and the surrounding landscape or seascape which protect the network from potentially damaging external influences and which are essentially transitional areas (Bennett & Mulongoy, 2006).

Burden
The resulting negative impacts of ecosystem use and management on people and nature, including distant, diffuse and delayed impacts (modified from Pascual *et al.*, 2017)

By-catch
The incidental capture of non-target species. The portion of a commercial fishing catch that consists of marine animals caught unintentionally (Merriam-Webster, 2015).

C

C3 photosynthesis
The major of the metabolic pathways for CO_2 fixation by plants, involving a 3-carbon organic intermediate molecule. C3 photosynthetic plants possess a specific leaf structure, and are not adapted to non-optimal conditions(Nature, 2018a).

C3 plants
Plants that use C3 photosynthesis to capture CO_2 (New South Wales Government, 2018).

C4 photosynthesis
C4 photosynthesis is an evolved metabolic mechanism for plant carbon fixation, in which atmospheric CO_2 is first incorporated into a 4-carbon intermediate molecule. It allows for a more efficient process compared to C3 photosynthesis, especially in non-optimal water availability conditions and in the presence of high solar radiation (Nature, 2018b).

C4 plants
Plants that use C4 photosynthesis to capture CO_2. The Poaceae family (grasses) accounts for about half of the C4 species (New South Wales Government, 2018; Osborne *et al.*, 2014).

Cap-and-trade
An economic policy instrument in which the State sets an overall environmental target (the cap) and assigns environmental impact allowances (or quotas) to actors that they can trade among each other.

Carbon cycle
The flow of carbon (in various forms, e.g., as carbon dioxide (CO_2)) through the atmosphere, ocean, terrestrial and marine biosphere and lithosphere (IPCC, 2014a).

Carbon footprint
A measure of the emission of gases that contribute to heating the planet in carbon dioxide (CO_2)-equivalents per unit of time or product; there is no universally-accepted definition of the term (Ercin & Hoekstra, 2012).

Carbon sequestration
The long-term storage of carbon in plants, soils, geologic formations, and the ocean. Carbon sequestration occurs both naturally and as a result of anthropogenic activities.

Carbon sink
Any process, activity or mechanism that removes carbon dioxide from the atmosphere (IPCC, 2014a).

Carbon uptake
See 'Carbon sequestration'

Carrying capacity
In ecology, the carrying capacity of a species in an environment is the maximum population size of the species that the environment can sustain indefinitely. The term is also used more generally to refer to the upper limit of habitats, ecosystems, landscapes, waterscapes or seascapes to provide tangible and intangible goods and services (including aesthetic and spiritual services) in a sustainable way.

Certification (environmental)
A procedure by which a third party gives written assurance that a product, process or service is in conformity with certain environmental standards (Dankers & Liu, 2003).

Certification principles and standards
A list of principles that certification schemes need to satisfy in order to be effective and credible.

Charismatic species
Any species that has popular appeal and is used to focus attention on conservation campaigns (Froese & Pauly, 2018).

Chemosynthesis
Synthesis of organic compounds (as in living cells) by energy derived from inorganic chemical reactions.

Circular economy
A regenerative system in which resource input and waste, emission, and energy leakage are minimized by slowing, closing, and narrowing material and energy loops. This can be achieved through long-lasting design, maintenance, repair, reuse, remanufacturing, refurbishing, and recycling (Geissdoerfer *et al.*, 2017).

Citizen science
Citizen science refers to research collaborations in which volunteers and scientists partner to answer real-world questions, typically through a connected interface. A major setback of citizen science

projects is that they may require some level of computer literacy and network connectivity, both rare in many rural areas of the world. Despite the challenge, some researchers have already been successful in implementing interactive multimedia web-based tools for the collection of data based on local monitoring systems (Ens, 2012; Gill & Lantz, 2014; Pulsifer *et al.*, 2010; Stevens *et al.,* 2014).

Clade
A group of organisms believed to comprise all the evolutionary descendants of a common ancestor (Oxford Living Dictionaries, 2018).

Climate change
A change in the state of the climate that can be identified (e.g., by using statistical tests) by changes in the mean and/or the variability of its properties and that persists for an extended period, typically decades or longer. Climate change may be due to natural internal processes or external forcings such as modulations of the solar cycles, volcanic eruptions and persistent anthropogenic changes in the composition of the atmosphere or in land use (IPCC, 2014a) (please see related definition for human-induced climate change below).

Collapse (social-ecological system)
The rapid and durable loss of a defined social-ecological system as such, resulting in substantial loss of social-ecological capital (e.g., biomass) (Cumming & Peterson, 2017).

Co-management
Process of management in which government shares power with resource users, with each given specific rights and responsibilities relating to information and decision-making (OECD, 2007b).

Community (ecological)
An assemblage of populations of at least two different species which coexist, and to various degrees interact directly and indirectly within a defined local geographic area and in a particular time; it is characterized in terms of taxonomic and functional composition (the species and functional types present) and richness (e.g., richness, abundance, dominance and distribution of species, or phenotypes) (Stroud *et al.*, 2015).

Community forestry
A broad term used to describe models of forest management that give local users the majority say in making decisions. Similar terms include participatory forest management, collaborative forest management, social forestry, and community-based forest management. With an aim to reduce poverty, community forestry is participatory and is intended to serve all community members equitably.

Community-based conservation
Institutions and/or processes involving community members in the protection of biodiversity aimed at promoting the coexistence of people and nature. This includes -but is not restricted to- Indigenous Peoples' and rural and coastal community conserved territories and areas (see 'ICCAs') (Western *et al.*, 1994).

Community-based monitoring
Processes involving the participation of community members in a range of observation and measurement activities to maintain awareness of ecological and social factors affecting a community (Bliss *et al.*, 2001).

Community-based natural resource management
A process by which local groups or communities organize themselves with varying degrees of interaction with state agencies and outside support so as to apply their skills and knowledge to the care of natural resources while satisfying livelihood needs (Pretty & Gujit, 1992).

Community-managed forests
Decentralized system of forest resource management designed to promote more equitable outcomes for stakeholders' livelihoods changing relationships between stakeholders, government agencies, and markets (adapted from Newton *et al.*, 2015).

Conservation agriculture
An approach to managing agroecosystems for improved and sustained productivity, increased profits and food security while preserving and enhancing the resource base and the environment. It is characterized by three linked principles, namely: 1) continuous minimum mechanical soil disturbance; 2) permanent organic soil cover; and 3) diversification of crop species grown in sequences and/or associations. This covers a wide range of approaches from minimum till to permaculture and "mimicking nature".

Conservation benefits
The positive impacts on people and ecosystems due to conservation.

Conservation biology
The branch of biological science concerned with the conservation, management, and protection of vulnerable species, populations, and ecosystems. Also see 'Biological conservation'.

Continental shelf
The gently sloping, shelf-like part of the seabed adjacent to the coast extending to a depth of about 200m (IUCN, 2012a).

Continental slope
The often steep, slope-like part of the seabed extending from the edge of the continental shelf to a depth of about 2,000m (IUCN, 2012a).

Co-production (of contributions between nature and people)
In the context of the IPBES conceptual framework, this is the joint contribution by nature and anthropogenic assets in generating nature's contributions to people (IPBES, 2016).

Coral bleaching
When water is too warm, corals will expel the algae (zooxanthellae) living in their tissues causing the coral to turn completely white. Corals can survive a bleaching event, but they are under more stress and are subject to mortality (NOAA, 2018d).

Corridor / biological corridor
A geographically defined area which allows species to move between landscapes, ecosystems and habitats, natural or modified, and is intended to ensure the maintenance of biodiversity and ecological and evolutionary processes.

Cosmic models
A vision of reality that places the highest importance or emphasis in the universe or nature, as opposite to an anthropocentric vision, which strongly focuses on humankind as the most important element of existence.

Cosmologies (or cosmogonies)
The ways any society develops worldviews that aim at explaining the content and the dynamics of the universe, its spatial and temporal properties, the types of living beings that inhabits it, the principles and energies that explains its origin and its future.

Country of origin of genetic resources
Country possessing genetic resources in *in situ* conditions (Convention on Biological Diversity, 1992).

Country providing genetic resources
Country supplying genetic resources collected from *in situ* sources, including populations of both wild and domesticated species, or taken from *ex situ* sources, which may or may not have originated in that country (Convention on Biological Diversity, 1992).

Crop wild relative
See 'Wild relative'.

Cross-pollination
The movement of pollen between the flowers of two distinct plants (IPBES, 2016).

Cryosphere
The components of the Earth system that contain a substantial fraction of water in a frozen state, i.e., sea ice, glaciers, ice sheets (National Snow and Ice Data Center (NSIDC), 2018).

Cultural change (or culture change)
Cultural change is a continuous process in any society, which can vary from gradual to stochastic, resulting from interactions between processes that are internal (e.g., needs, local changes, crisis, mobility, ideas, invention and innovation, conflicts, etc.) and external (e.g., diffusion, external agents, political and economic forces, conflicts, etc.) (Berry, 2008; Redfield *et al.*, 1936). Cultural change is interpreted differently depending on theoretical orientation, such as diffusionism, modernization theory, world system theory, neocolonialism, globalization, among others (see Peña, 2005; Rudmin, 2009; Santos-Granero, 2009). Culture change can be selective or systemic and most often involves resistance and conflicts but can also lead to adaptation and resilience in changing contexts and environments.

Cultural ecosystem services
A category of ecosystem services first developed in the Millenium Ecosystem Assessment (2005) to refer to the nonmaterial benefits people obtain from ecosystems through spiritual enrichment, cognitive development, reflection, recreation, and aesthetic experience, including, e.g., knowledge systems, social relations, and aesthetic values (Millenium Ecosystem Assessment, 2005). In the Global Assessment, cultural ecosystem services are included as part of both material and non-material nature's contributions to people (see chapter 1).

Cultural keystone species / culturally important species
The culturally salient species that shape in a major way the cultural identity of a people, as reflected in the fundamental roles these species have in diet, materials, medicine, and/or spiritual practices (Garibaldi & Turner, 2004).

Cultural landscapes
Cultural landscapes express the long-term co-evolution relationships between people and nature, influenced by internal and external forces affecting the aesthetic and productive configuration of land management, water bodies, wildlife, property systems, infrastructure and human settlements, and which are both a source and a product of changing social, institutional, economic, and cultural systems (also see WHC, 2008).

Cultural values
Cultural values are shared social values and norms, which are learned and dynamic, and which underpin attitudes and behaviour and how people respond to events and opportunities, and affects the hierarchy of values people assign to objects, knowledge, stories, feelings, other beings, forms of social expressions, and behaviours.

Culture
There is no single definition of culture. A commonly accepted definition of culture refers to the system of shared beliefs, values, customs, behaviours, and artifacts, and the meanings attributed to them, that the members of society use to cope and interact with the world and one another, and that are transmitted from generation to generation through learning (Bates & Plog, 1990).

Customary land tenure
The socially-embedded systems and institutions used within communities to regulate and manage land use and access, and which derive from the community itself rather than from the state.

Customary law
Law consisting of customs that are accepted as legal requirements or obligatory rules of conduct; practices and beliefs that are so vital and intrinsic a part of a social and economic system that they are treated as if they were laws (CBD, 2018b).

Customary rights
Rights, such as land rights or political rights, that are granted by either customary or statutory law. Customary rights exist where there is a consensus of relevant actors considering them to be 'law'.

Customary sustainable use
Uses of biological resources in accordance with traditional cultural practices that are compatible with conservation or sustainable use requirements (CBD, 2018b).

D

Deforestation
Human-induced conversion of forested land to nonforested land. Deforestation can be permanent, when this change is maintained and definitive, or temporary when this change is part of a cycle that includes natural or assisted regeneration.

Degraded lands
Land in a state that results from persistent decline or loss of biodiversity and ecosystem functions and services that cannot fully recover unaided within decadal timescales.

Demographic transition
A model describing transition in demographic profile of a population, which has been associated with the development process that transforms an agricultural society into an industrial one and characterized by a rapid population growth due to a decline in the death rate while fertility remains high initially; the growth rate then declines due to a decline in the birth rate. Before the transition's onset, population growth is low as high death rates tend to offset high fertility. After the transition, population growth is again below replacement level as both birth and death rates reach low levels (Bongaarts, 2009).

Denitrification
The reduction of nitrates and nitrites to nitrogen by microorganisms.

Deoxygenation (ocean)
Decreased oxygen concentrations in the ocean, as a result of climate change and other anthropogenic stressors, e.g., nutrient input due to inefficient fertilizer use (Isensee & Valdes, 2015).

Desertification
Desertification means land degradation in arid, semi-arid and dry sub-humid areas resulting from various factors, including climatic variations and human activities. Desertification does not refer to the natural expansion of existing deserts (UNCCD, 2014).

Dispersal
Movement of individuals (and in some species, their gametes) that has the potential for moving genes through space (Templeton, 2017).

Domesticated species
Species in which the evolutionary process has been influenced by humans to meet their needs (Convention on Biological Diversity, 1992).

Domestication
Evolutionary process driven by human (whether conscious or unconscious) selection but also involving natural processes applied to wild plants or animals and leading to adaptation to cultivation and consumption or utilization. Domestication can be complete, whereby organisms become entirely dependent on humans for their continued existence or can be partial or incipient, whereby they still reproduce independently of human intervention (Gepts, 2014). In traditional systems, farming practices still shape the genetic structure of crops and their evolution (Vigouroux *et al.*, 2011).

Downscaling
Downscaling is a method that derives local- to regional scale information from larger-scale models or data analyses (IPCC, 2014b). It is the opposite of upscaling.

Drivers of change
Drivers of change refer to all those external factors that affect nature, and, as a consequence, also affect the supply of nature's contributions to people. The IPBES conceptual framework includes drivers of change as two of its main elements: indirect drivers, which are all anthropogenic, and direct drivers, both natural and anthropogenic. See chapter 1 and chapter 2 (Drivers) for a detailed typology of drivers.

Drivers (direct)
Drivers, both non human-induced and anthropogenic, that affect nature directly. Direct anthropogenic drivers are those that flow from human institutions and governance systems and other indirect drivers. They include positive and negative effects, such as habitat conversion, human-caused climate change, or species introductions. Direct non human-induced drivers can directly affect anthropogenic assets and quality of life (e.g., a volcanic eruption can destroy roads and cause human deaths), but these impacts are not the main focus of IPBES. See chapter 1 and chapter 2.1 (Drivers) for a detailed typology of drivers.

Drivers (indirect)
Human actions and decisions that affect nature diffusely by altering and influencing direct drivers as well as other indirect drivers. They do not physically impact nature or its contributions to people. Indirect drivers include economic, demographic, governance, technological and cultural ones, among others. See chapter 1 and chapter 2 (Drivers) for a detailed typology of drivers.

E

Earth Jurisprudence
An emerging field of law that seeks to develop a philosophy and practice of law that gives greater consideration to nature, by recognizing the interconnectedness of Earth's natural systems, the inherent rights and value of nature, and the dependence of humanity and all living beings on a healthy Earth (United Nations, 2015).

Ecological connectivity
See 'Habitat connectivity'

Ecological disturbance (natural and anthropogenic)
An event that can disrupt any ecological level, environmental component as well as the organizational status of a biological cycle of organisms. Disturbances are an important aspect in the natural selection and the whole biological evolution, as they modify the environment in which every living being performs its vital functions (Battisti *et al.*, 2016).

Ecological footprint
A measure of the amount of biologically productive land and water required to support the demands of an individual, a population or productive activity. Ecological footprints can be calculated at any scale: for an activity, a person, a community, a city, a region, a nation or humanity as a whole.

Ecoregion
A large area of land or water that contains a geographically distinct assemblage of natural communities that:
(a) Share a large majority of their species and ecological dynamics;
(b) Share similar environmental conditions, and;
(c) Interact ecologically in ways that are critical for their long-term persistence (Olson *et al.*, 2004). In contrast to biomes, an ecoregion is generally geographically specific, is at a much finer scale, and contains ecologically interacting biota. For example, the "East African Montane Forest" eco-region of Kenya (WWF ecoregion classification, Olson and Dinerstein, 2002) is a geographically specific and coherent example of the globally occurring "tropical and subtropical forest" biome.

Ecosystem
A dynamic complex of plant, animal and micro-organism communities and their non-living environment interacting as a functional unit (Convention on Biological Diversity, 1992).

Ecosystem approach
See 'Ecosystem-based approach'.

Ecosystem ecology
The integrated study of biotic and abiotic components of ecosystems and their interactions within an ecosystem framework. This science examines physical and biological structures and examines how these ecosystem characteristics interact with each other (Simon *et al.*, 2010).

Ecosystem engineer
Organism that changes the abiotic environment by physically altering structure, which often have effects on other biota and their interactions, and on ecosystem processes (Gutiérrez & Jones, 2008).

Ecosystem function
The flow of energy and materials through the biotic and abiotic components of an ecosystem. It includes many processes such as biomass production, trophic transfer through plants and animals, nutrient cycling, water dynamics and heat transfer.

Ecosystem integrity
The ability of an ecosystem to support and maintain ecological processes and a diverse community of organisms. It is measured as the degree to which a diverse community of native organisms is maintained, and is used as a proxy for ecological resilience, intended as the capacity of an ecosystem to adapt in the face of stressors, while maintaining the functions of interest (Ocean Health Index, 2018).

Ecosystem sensitivity
The degree to which an ecosystem is affected, either adversely or beneficially,

by climate related stimuli, including mean (average) climate characteristics, climate variability and the frequency and magnitude of extremes (IUCN, 2012a).

Ecosystem services
The benefits people obtain from ecosystems. According to the original formulation of the Millennium Ecosystem Assessment, ecosystem services were divided into supporting, regulating, provisioning and cultural. See chapter 1 for the equivalence of the concept to the concept of nature's contribution to people predominantly used in this assessment

Ecosystem structure
The individuals and communities of plants and animals of which an ecosystem is composed, their age and spatial distribution, and the non-living natural resources present (IUCN, 2012a).

Ecosystem-based adaptation
The conservation, sustainable management and restoration of natural ecosystems to help people adapt to climate change (Colls *et al.*, 2009).

Ecosystem-based approach
A strategy for the integrated management of land, water and living resources that promotes conservation and sustainable use in an equitable way. An ecosystem approach is based on the application of appropriate scientific methods, focused on levels of biological organization that encompass the essential structure, processes, functions and interactions among and between organisms and their environment. It recognizes that humans, with their cultural diversity, are an integral component of many ecosystems (UNEP, 2012).

Ectotherms
Often referred to as cold-blooded and applied to organisms that cannot regulate their body temperature relative to the surrounding environment, i.e., deriving heat from outside the body (FAO, 2018a).

Edge effects
A change in species composition, physical conditions or ecological factors at the boundary between two or more habitats (IUCN, 2012a).

El Niño / La Niña
The term El Niño was initially used to describe a warm-water current that periodically flows along the coast of Ecuador and Perú, disrupting the local fishery. It has since become identified with a basin-wide warming of the tropical Pacific Ocean east of the dateline. This oceanic event is associated with a fluctuation of a global-scale tropical and subtropical surface pressure pattern called the Southern Oscillation. This coupled atmosphere-ocean phenomenon, with preferred time scales of two to about seven years, is collectively known as the El Niño-Southern Oscillation (ENSO) (IPCC, 2014a).

Empowerment
The process by which people gain control over the factors and decisions that shape their lives. It is the process by which they increase their assets and attributes and build capacities to gain access, partners, networks and/or a voice, in order to gain control (WHO, 2010).

Endangered species
A species at risk of extinction in the wild.

Endemic species
Species that is native to, and restricted to, a particular geographical region. Highly endemic species, those with very restricted natural ranges, are especially vulnerable to extinction if their natural habitat is eliminated or significantly disturbed (IUCN, 2012a).

Energy source
Primary energy sources take many forms, including nuclear energy, fossil energy -like oil, coal and natural gas, biomass- and renewable sources like wind, solar, geothermal and hydropower. These primary sources are converted to electricity, a secondary energy source (US Department of Energy, 2018).

Environmental education
The facilitation of an integrated perception of the problems of the environment, enabling more rational actions capable of meeting social needs to be taken (UNESCO, 1978).

Environmental envelope
The environmental envelope of a species is defined as the set of environments within which it is believed that the species can persist: that is where its environmental requirements can be satisfied (see niche). Many large-scale vegetation or species models are based on environmental envelope techniques (Walker & Cocks, 1991).

Environmental gradients
Environmental characteristics that explain the distribution of organisms and ecosystems in terms of environmental tolerances (Government of New Brunswick, 2007).

Environmental Impact Assessment
A formal, evidence-based procedure that assesses the economic, social, and environmental effects of public policy, such as the construction of large-scale infrastructure, or of any human activity.

Environmental justice
The fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation and enforcement of environmental laws, regulations and policies (US Environmental Protection Agency, 2018a).

Environmental Kuznets Curve (EKC)
The hypothesis of an inverted U-shaped relationship between economic output per capita and some measures of environmental quality: as GDP per capita rises, so does environmental degradation. However, beyond a certain point, increases in GDP per capita lead to reductions in environmental damage (Everett *et al.*, 2010).

Environmental taxes / green taxes
A tax whose tax base is a physical unit (or a proxy of it) that has a proven specific negative impact on the environment. Four subsets of environmental taxes are distinguished: energy taxes, transport taxes, pollution taxes and resources taxes (OECD, 2005a).

Epifauna
Animals living on or just above the seabed (IUCN, 2012a).

Epistemic community
A professional network with recognized expertise and competence, and a claim for policy-relevant knowledge, in a particular domain (Haas, 1992).

Essential Biodiversity Variables (EBV)
Essential Biodiversity Variables are promoted by the Group on Earth Observations Biodiversity Observation Network (GEO BON). The idea behind this concept is to identify, using a systems approach, the key variables that should be monitored in order to measure biodiversity change. The Essential Biodiversity Variables are an intermediate layer of abstraction between raw data, from *in situ* and remote sensing observations, and derived high-level indicators used to communicate the state and trends of biodiversity.

Ethnobiology
The study of dynamic relationships among peoples, biota, and environments, as encoded in the knowledge held by different societies and individuals. Its multidisciplinary nature allows it to examine complex, dynamic interactions between human and natural systems, and enhances our intellectual merit and broader impacts (Society of Ethnobiology, 2018).

Eutrophic/eutrophicated habitats
A condition of an aquatic system in which increased nutrient loading leads to progressively increasing amounts of algal growth and biomass accumulation. When the algae die off and decompose, the amount of dissolved oxygen in the water becomes reduced.

Eutrophication
An enrichment of water by nutrients that causes structural changes to the ecosystem, such as: increased production of algae and aquatic plants, depletion of fish species, general deterioration of water quality and other effects that reduce and preclude use (OECD, 1982).

Evapotranspiration
The sum of water loss from both plants and soil measured over a specific area (IUCN, 2012a).

Evenness (biodiversity)
In ecology, species evenness refers to the similarity of abundances of each species in an environment. It can be quantified by a diversity index as a dimension of biodiversity.

Evolutionary anthropology
The interdisciplinary study of the evolution of human physiology and human behaviour and the relation between hominids and non-hominid primates. Evolutionary anthropology is based in the natural and social sciences (McGee, 2003).

Evolutionary biology
A subdiscipline of the biological sciences concerned with the origin of life and the diversification and adaptation of life forms over time (Nature, 2018c).

Exclusive economic zones (EEZs)
An Exclusive Economic Zone (EEZ) is a concept adopted at the Third United Nations Conference on the Law of the Sea (1982), whereby a coastal State assumes jurisdiction over the exploration and exploitation of marine resources in its adjacent section of the continental shelf, taken to be a band extending 200 miles from the shore. The Exclusive Economic Zone (EEZ) comprises an area which extends either from the coast, or in federal systems from the seaward boundaries of the constituent states (3 to 12 nautical miles, in most cases) to 200 nautical miles (370 kilometres) off the coast. Within this area, nations claim and exercise sovereign rights and exclusive fishery management authority over all fish and all Continental Shelf fishery resources (United Nations, 1997).

Extinction
A population, species or more inclusive taxonomic group has gone extinct when all its individuals have died. A species may go extinct locally (population extinction), regionally (e.g., extinction of all populations in a country, continent or ocean) or globally. Populations or species reduced to such low numbers that they are no longer of economic or functional importance may be said to have gone economically or functionally extinct, respectively. Species extinctions are typically not documented immediately: for example, the IUCN Red List categories and criteria require there to be no reasonable doubt that all individuals have died, before a species is formally listed as Extinct (see IUCN Red List, 2012b).

Extinction debt
Local, regional or global extinctions that have not yet taken place, but which have been set in train by environmental impacts - such as habitat destruction, degradation and fragmentation - that have already taken place and that have reduced the site, region or world's carrying capacity for species. Species or populations that make up the extinction debt can be said to be "committed to extinction". The length of time taken to repay the extinction debt is known as the relaxation time, and depends on multiple factors (Kuussaari *et al.*, 2009).

F

Fallow
Land normally used for production and left to recover for part or all of a growing season or in cycles that can vary from few years to decades, such as in the case of swidden agriculture (Gleave, 1996; United Nations, 1997).

Family forestry
Family forestry is forest tenure and activities by persons with ownership or tenure rights to forest land. Persons owning or managing forests often include the extended family in the activities and the forest land goes from one generation to the next (International Family Forestry Alliance, 2016).

Fishery
A unit determined by an authority or other entity that is engaged in raising and/or harvesting fish. Typically, the unit is defined in terms of some or all of the following: people involved, species or type of fish, area of water or seabed, method of fishing, class of boats and purpose of the activities (FAO, 2001a).

Fitness (ecology)
Fitness involves the ability of organisms— or populations or species— to survive and reproduce in the environment in which they find themselves, and thus contribute genes to the next generation (Orr, 2009).

Folk biology
People's everyday understanding of the biological world—how they perceive, categorize, and reason about living kinds (Medin & Atran, 1999).

Folk categories
The units of meaning into which a language breaks up the universe for example, folk plant and animal taxa (Berlin, 1973).

Food security
The World Food Summit of 1996 defined food security as existing "when all people at all times have access to sufficient, safe, nutritious food to maintain a healthy and active life".

Food web / food web interactions
An important ecological concept representing feeding relationships within a community and implying the transfer of food energy from its source in plants through herbivores to carnivores; normally, food webs consist of a number of food chains meshed together (Hui, 2012).

Forest
A vegetation type dominated by trees. Definitions of forest varies according to the use of parameters such as biogeography, physiognomy, biomass, human management, species dominance and composition, among others, therefore affecting estimates of extent and type of change (also see IPCC, 2014a).

Forest degradation
A process leading to a temporary or permanent deterioration in the density or

structure of vegetation cover or its species composition. It is a change in forest attributes that leads to a lower productive capacity caused by an increase in disturbances. Continued degradation of the forests can destroy the entire forest cover and biodiversity, and it mainly occurs because of environmental and anthropogenic changes (Tejawasi, 2007).

Forest garden
A range of systems for the management of forest resources that are intermediate on a continuum between pure extraction and plantation management, and ranging from wild forests modified for increased production of selected products (e.g., fruit and nut trees) to anthropogenic forests with a high density of valuable species within a relatively diverse and complex structure (Belcher *et al.*, 2005).

Forest Law Enforcement, Governance and Trade (FLEGT)
A reduction of illegal logging by strengthening sustainable and legal forest management, improving governance and promoting trade in legally produced timber (EUFLEGT Facility, 2018a).

Forest transition
Attributed to Mather (1992), this term denotes a process of land-use change in a country or region with a period of decline in forest cover, during earlier economic development, then forest recovery.

Fossil fuels
Fossil fuels are derived from the remains of ancient plant and animal life: coal, oil and natural gas. In common dialogue, the term fossil fuel also includes hydrocarbon-containing natural resources that are not derived from animal or plant sources (OECD, 2001a).

Free, prior and informed consent (FPIC) / prior, informed consent
Free implies that Indigenous Peoples and Local Communities are not pressured, intimidated, manipulated or unduly influenced and that their consent is given, without coercion; prior implies seeking consent or approval sufficiently in advance of any authorization to access traditional knowledge respecting the customary decision-making processes in accordance with national legislation and time requirements of Indigenous Peoples and Local Communities; informed implies that information is provided that covers relevant aspects, such as: the intended purpose of the access; its duration and scope; a preliminary assessment of the likely economic, social, cultural and environmental impacts, including potential risks; personnel likely to be involved in the execution of the access; procedures the access may entail and benefit-sharing arrangements; consent or approval is the agreement of the Indigenous Peoples and Local Communities who are holders of traditional knowledge or the competent authorities of those Indigenous Peoples and Local Communities, as appropriate, to grant access to their traditional knowledge to a potential user and includes the right not to grant consent or approval (derived from CBD, 2018b).

Functional diversity
The range, values, relative abundance and distribution of functional traits in a given community or ecosystem (Diaz *et al.*, 2007).

Functional extinction
See 'Exctinction'.

Functional group
A collection of organisms with similar suites of co-occurring functional attributes. Groups are traditionally associated with similar responses to external factors and/or effects on ecosystem processes. A functional group is often referred to as 'guild', especially when referring to animals, e.g., the feeding types of aquatic organisms having the same function within the trophic chain (De Bello *et al.*, 2010).

Functional redundancy
The occurrence in the same ecosystem of species filling similar roles, which results in a sort of "insurance" in the ecosystem, with one species able to "replace" a similar species from the same functional niche (Rosenfeld, 2002).

Functional traits
Any feature of an organism, expressed in the phenotype and measurable at the individual level, which has demonstrable links to the organism's function (Lavorel *et al.*, 1997; Violle *et al.*, 2007). As such, a functional trait determines the organism's response to external abiotic or biotic factors (Response trait), and/or its effects on ecosystem properties or benefits or detriments derived from such properties (Effect trait). In plants, functional traits include morphological, ecophysiological, biochemical and regeneration traits. In animals, these traits include e.g., body size, litter size, age of sexual maturity, nesting habitat, time of activity.

G

Gene
The basic physical and functional unit of heredity. Genes are made up of DNA, and occupy a fixed position (locus) on a chromosome. Genes achieve their effects by directing the synthesis of proteins (Encyclopaedia Britannica, 2018).

Gene flow
The movement of individuals, and/or the genetic material they carry, from one population to another. Gene flow includes lots of different kinds of events, such as pollen being blown to a new destination or people moving to new cities or countries (University of California Museum of Paleontology, 2018a).

Generalist species
A species able to thrive in a wide variety of environmental conditions and that can make use of a variety of different resources (for example, a flower-visiting insect that lives on the floral resources provided by several to many different plants).

Genetic composition
The composition in alleles of a population (University of Leicester, 2018).

Genetic diversity
The variation at the level of individual genes, which provides a mechanism for populations to adapt to their ever-changing environment. The more variation, the better the chance that at least some of the individuals will have an allelic variant that is suited for the new environment, and will produce offspring with the variant that will in turn reproduce and continue the population into subsequent generations (NBII, 2011).

Genetic engineering
The artificial manipulation, modification, and recombination of DNA or other nucleic acid molecules in order to modify an organism or population of organisms.

Genetic erosion
The loss of genetic diversity, including the loss of individual genes or particular combinations of genes, and loss of varieties and crops (Vetriventhan *et al.*, 2016).

Genetic resources
Genetic material of actual or potential value (Convention on Biological Diversity, 1992).

Genetically Modified Organism (GMO)
Organism in which the genetic material (DNA) has been altered in a way that does not occur naturally by mating and/or natural recombination (WHO, 2014). The Cartagena Protocol on Biosafety defines ‘living modified organism’ as any living organism that possesses a novel combination of genetic material obtained through the use of modern biotechnology (CBD, 2000).

Genotype
The genetic constitution of an individual or group (IUCN, 2012a).

Germplasm
Living tissue from which new plants can be grown. It can be a seed or another plant part – a leaf, a piece of stem, pollen or even just a few cells that can be turned into a whole plant (University of California Seed Biotechnology Center, 2018).

Gini index
The Gini index measures the extent to which the distribution of income (or, in some cases, consumption expenditure or other variables) among individuals or households within an economy deviates from a perfectly equal distribution. A Gini index of 0 represents perfect equality, while an index of 100 implies perfect inequality (World Bank, 2018).

Global commons or global common pool resources (CPR)
Common pool resources (CPR) that have a global nature, such as the atmosphere, the oceans, global species diversity, migratory species, global biogeochemical processes, among others. It does not refer to property rights, such as a common property system. In general, CPR include natural and human-constructed resources in which (i) exploitation by one user reduces resource availability for others, and (ii) exclusion of beneficiaries through physical and institutional means is especially costly. These two characteristics – difficulty of exclusion and subtractability – create potential CPR dilemmas in which people following their own short-term interests produce outcomes that are not in anyone’s long-term interest (Ostrom *et al.*, 1994).

Global North – Global South
The Global South and the Global North is a terminology that distinguishes not only between political systems or degrees of poverty, but between the victims and the benefactors of global capitalism (Wolvers *et al.*, 2015).

Good Quality of Life (GQL)
Within the context of the IPBES Conceptual Framework – the achievement of a fulfilled human life, a notion which may varies strongly across different societies and groups within societies. It is a context-dependent state of individuals and human groups, comprising aspects such as access to food, water, energy and livelihood security, and also health, good social relationships and equity, security, cultural identity, and freedom of choice and action. “Human wellbeing”, “inclusive wealth”, “living in harmony with nature”, “living-well in balance and harmony with Mother Earth” are examples of different perspectives on a “Good quality of life”. See detailed description in chapter 1.

Governance
A comprehensive and inclusive concept of the full range of means for deciding, managing, implementing and monitoring actions and measures, including policies. Whereas government is defined strictly in terms of the nation-state, the more inclusive concept of governance recognizes the contributions of various levels of government (global, international, regional, sub-national and local) and the contributing roles of the private sector, of nongovernmental actors, and of civil society to addressing the many types of issues from local to global levels (adapted from IPCC, 2018).

Great Acceleration
Great Acceleration refers to the acceleration of human-induced changes of the second half of the 20th century, unique in scale in the history of human existence. Many human activities reached take-off points and sharply accelerated since the 1950s with world regions changing their contributions to globally-aggregated changes over time (adapted from International Geosphere-Biosphere Programme, 2015).

Green bonds
A mode of private financing that tap the debt capital market through fixed income instruments (i.e., bonds) to raise capital to finance climate-friendly projects in key sectors of, but not limited to, transport, energy, building and industry, water, agriculture and forestry and waste (OECD, 2017).

Green growth
Green growth means fostering economic growth and development while ensuring that natural assets continue to provide the resources and environmental services on which our well-being relies (OECD, 2018a).

Green infrastructure / grey infrastructure
Green infrastructure refers to the natural or semi-natural systems (e.g., riparian vegetation) that provide services for water resources management with equivalent or similar benefits to conventional (built) “grey” infrastructure (e.g., water treatment plants) (UNEP, 2014).

Green Revolution
A term attributed to a period of food crop productivity growth that started in the 1960s due to a combination of high rates of investment in crop research, infrastructure, market development, and policy support, and whose environmental impacts have been mixed: on the one side, it is said to have contributed to saving land conversion to agriculture, on the other side, it is said to have contributed to promoting an overuse of inputs and cultivation on areas otherwise improper to high levels of intensification, such as slopes, and high levels of pesticide pollution (adapted from Pingali, 2012). It is also argued that development policies promoting the Green Revolution contributed to undermine otherwise productive and resilient locally-based food production systems.

Greenhouse gases (GHGs)
Greenhouse gases are those gaseous constituents of the atmosphere, both natural and anthropogenic, that absorb and emit radiation at specific wavelengths within the spectrum of terrestrial radiation emitted by the Earth’s surface, the atmosphere itself, and by clouds. This property causes the greenhouse effect. Water vapour (H_2O), carbon dioxide (CO_2), nitrous oxide (N_2O), methane (CH_4) and ozone (O_3) are the primary greenhouse gases in the Earth’s atmosphere. Moreover, there are a number of entirely human-made greenhouse gases in the atmosphere, such as the halocarbons and other chlorine- and brominecontaining substances, dealt with under the Montreal Protocol. Beside CO_2, N_2O and CH_4, the Kyoto Protocol deals with the greenhouse gases sulphur hexafluoride (SF6), hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs) (IPCC, 2014a).

Gross primary productivity
The amount of carbon fixed by the autotrophs (e.g., plants and algaes) (IPCC, 2014a).

Habitat
The place or type of site where an organism or population naturally occurs. Also used to mean the environmental attributes required by a particular species or its ecological niche.

Habitat connectivity
The degree to which the landscape or waterscape facilitate the movement of organisms (animals, plant reproductive structures, pollen, pollinators, spores, etc.) and other environmentally important resources (e.g., nutrients and moisture) between similar habitats. Connectivity is hampered by fragmentation (q.v.).

Habitat degradation
A general term describing the set of processes by which habitat quality is reduced. Habitat degradation may occur through natural processes (e.g., drought, heat, cold) and through human activities (forestry, agriculture, urbanization). It is sometimes used as a synonym of habitat deterioration or nature deterioration.

Habitat fragmentation
A general term describing the set of processes by which habitat loss results in the division of continuous habitats into a greater number of smaller patches of lesser total and isolated from each other by a matrix of dissimilar habitats. Habitat fragmentation may occur through natural processes (e.g., forest and grassland fires, flooding) and through human activities (forestry, agriculture, urbanization).

Habitat heterogeneity
The number of different habitats in a landscape (Cramer & Willig, 2005).

Habitat modification
Changes in an area's primary ecological functions and species composition due to human activity and/or non-native species invasion (UNEP-WCMC, 2014).

Habitat specialist
Species that require very specific habitats and resources (e.g., narrow range of food sources or cover types) to thrive and reproduce (Maryland State Wildlife Action Plan, 2015).

Harmful algal blooms (HABs)
Harmful algal blooms (HABs) occur when colonies of algae grow out of control and produce toxic or harmful effects on people, fish, shellfish, marine mammals and birds. The human illnesses caused by HABs, though rare, can be debilitating or even fatal (NOAA, 2016).

Heat island effect
Describes built up areas that are hotter than nearby rural areas. Heat islands can affect communities by increasing summertime peak energy demand, air conditioning costs, air pollution and greenhouse gas emissions, heat-related illness and mortality, and water quality (US Environmental Protection Agency, 2018b).

Holocene
The Holocene is the current geological epoch. It began after the Pleistocene, approximately 11,650 calendar years before present.

Homegarden
Areas surrounding a house for vegetable and fruit production and keeping of domestic animals. In many regions homegardens contain wild species utilized as medicinal plants, timber or other uses (Walker *et al.*, 2009).

Homeotherms
Organisms (vertebrates) with a constant and high body temperature, with a high level of energy exchange (Ivanov, 2006).

Hotspot of agrobiodiversity
Areas with significantly high levels of agrobiodiversity.

Hotspot of endemism
See 'Biodiversity hotspot'

Human appropriation of net primary production (HANPP)
The aggregate impact of land use on biomass available each year in ecosystems (Haberl *et al.*, 2007).

Human capital
Human capital is the stock of skills that people possess. It encompasses the notion that there are investments in people (e.g., education, training, health) and that these investments increase an individual's productivity (Goldin, 2016). In the IPBES conceptual framework, human capital is part of anthropogenic assets.

Human history
A general term used to refer to pre-historical and historical periods describing the development of humanity. Different classifications of periods exist reflecting different interpretation of human history.

Human-induced climate change
Note that the United Nations Framework Convention on Climate Change (UNFCCC), in its Article 1 of the UNFCCC, "a change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods" The UNFCCC thus makes a distinction between climate change attributable to human activities altering the atmospheric composition and climate variability attributable to natural causes (IPCC, 2014a) (please see related definition for climate change above).

Hunting
The capture by humans of wild mammals, birds, and reptiles, whether dead or alive, irrespective of the techniques used to capture them or the reasons to do so (Bennett & Robinson, 2000).

Hypoxia
Low dissolved oxygen levels in coastal and oceanic waters (<2mL per liter of water), either naturally occurring or as a result of a degradation (e.g., eutrophication) (Altieri *et al.*, 2017; Diaz & Rosenberg, 2008).

I

Identity
The ways in which people understand who they are, their belonging and role in society, and their relation to their broader environment (Fearon, 1999; Ingalls & Stedman, 2017). Identity can be multiple and situational.

Illegal logging
The harvesting, processing, transporting, buying or selling of timber in contravention of national and international laws (EUFLEGT Facility, 2018b).

Illegal, unreported and unregulated (IUU) fishing
A broad term which includes: fishing and fishing-related activities conducted in contravention of national, regional and international laws; non-reporting, misreporting or under- reporting of information on fishing operations and their catches; fishing by "Stateless" vessels; fishing in convention areas of Regional Fisheries Management Organizations (RFMOs) by non-party vessels; fishing activities which are not regulated by States and cannot be easily monitored and accounted for (FAO, 2016).

***In situ* conservation of biodiversity and agrobiodiversity**
The conservation of ecosystems and natural habitats and the maintenance and recovery of viable populations of species in their natural surroundings and, in the case of domesticated or cultivated species, in the surroundings where they have developed their distinctive properties (Convention on Biological Diversity, 1992)

Indicator
A quantitative or qualitative factor or variable that provides a simple, measurable and quantifiable characteristic or attribute responding in a known and communicable way to a changing environmental condition, to a changing ecological process or function, or to a changing element of biodiversity.

Indigenous and local knowledge (ILK)
The knowledge, practices and innovations embedded in the relationships of Indigenous Peoples and Local Communities to nature. ILK is situated in a place and social context, but at the same time open and hybrid, continuously evolving through the combination of written, oral, tacit, practical, and scientific knowledge attained from various sources, and validated by experimentation and in practice of direct interaction with nature. See chapter 1 (section 1.3.2.1) and chapter 2.2 (section 2.2.2) for a discussion on the differences between 'indigenous knowledge' and 'local knowledge'.

Indigenous and local knowledge (ILK) systems
Indigenous and local knowledge systems are social and ecological knowledge practices and beliefs pertaining to the relationship of living beings, including people, with one another and with their environments. Such knowledge can provide information, methods, theory and practice for sustainable ecosystem management.

Indigenous Peoples and Local Communities (IPLCs)
The Convention on Biological Diversity does not define the terms indigenous and local communities or Indigenous Peoples and Local Communities. The United Nations Declaration on the Rights of Indigenous Peoples does not adopt or recommend a universal definition for Indigenous Peoples (Decision CBD/COP/DEC/14/13). As used in the global assessment, Indigenous Peoples and Local Communities (IPLCs) is a term used internationally by representatives, organizations, and conventions to refer to individuals and communities who are, on the one hand, self-identified as indigenous and, on the other hand, are members of local communities that maintain inter-generational connection to place and nature through livelihood, cultural identity and worldviews, institutions and ecological knowledge. The term is not intended to ignore differences and diversity within and among Indigenous Peoples and between them and local communities; Indigenous Peoples have recognized and distinct rights, which are not extendable to the broader and encompassing concept of local communities. See chapter 1 (Section 1.3.2.1).

Indigenous Peoples' and community conserved territories and areas (ICCAs)
Natural and/or modified ecosystems containing significant biodiversity values, ecological services and cultural values, voluntarily conserved by Indigenous Peoples and Local Communities, both sedentary and mobile, through customary laws or other effective means (CBD, 2018b).

Individual fishing quotas (IFQs)
An allocation to an individual (a person or a legal entity (e.g., a company)) of a right [privilege] to harvest a certain amount of fish in a certain period of time. It is also often expressed as an individual share of an aggregate quota, or total allowable catch (TAC) (OECD, 2001b).

Individual transferable quotas (ITQs)
A type of quota (a part of a Total Allowable Catch) allocated to individual fishermen or vessel owners and which can be sold to others (OECD, 2005b).

Infauna
Animals that live within the sediment (IUCN, 2012a).

Institutions
Institutions encompass formal and informal rules and norms that structure individual and collective behaviour, including interactions among stakeholders and social structures that help to define how decisions are taken and implemented, how power is exercised, and how responsibilities are distributed.

Insular systems
Any area of habitat suitable for a specific ecosystem, surrounded by an expanse of unfavorable habitat that limits the dispersal of individuals. Insular systems can be either physical islands or isolated habitats (e.g., resulting of fragmentation) (Brown, 1978).

Integrated Assessment Models (IAMs)
Interdisciplinary models that aim to describe the complex relationships between environmental, social, and economic drivers that determine current and future state of the ecosystem and the effects of global change, in order to derive policy-relevant insights. One of the essential characteristics of integrated assessments is the simultaneous consideration of the multiple dimensions of environmental problems.

Integrated pest management (IPM)
Integrated Pest Management (IPM) is an ecosystem approach to crop production and protection that combines different management strategies and practices to grow healthy crops and minimize the use of pesticides (FAO, 2018b).

Integrated Water Resource Management (IWRM)
A process which promotes the coordinated development and management of water, land and related resources, in order to maximize the resultant economic and social welfare in an equitable manner without compromising the sustainability of vital ecosystems (Hassing *et al.*, 2009).

Intellectual property rights
Intellectual property rights are the rights given to persons over the creations of their minds. They usually give the creator an exclusive right over the use of his/her creation for a certain period of time. Intellectual property rights are customarily divided into two main areas: rights related to copyright and industrial property (World Trade Organization, 2018).

Intercropping
Refers to growing two or more crops in the same field at the same time (FAO, 2018a).

Intermediate disturbance hypothesis
The intermediate disturbance hypothesis (IDH) suggests that local species diversity is maximized when ecological disturbance is neither too rare nor too frequent (Connell, 1978).

Invasive alien species (IAS)
Species whose introduction and/or spread by human action outside their natural distribution threatens biological diversity, food security, and human health and well-being. "Alien" refers to the species'

having been introduced outside its natural distribution ("exotic", "non-native" and "non-indigenous" are synonyms for "alien"). "Invasive" means "tending to expand into and modify ecosystems to which it has been introduced". Thus, a species may be alien without being invasive, or, in the case of a species native to a region, it may increase and become invasive, without actually being an alien species.

IPBES conceptual framework
A simplified representation of the complex interactions between the natural world and human societies. This framework emerged from an extensive process of consultation and negotiation, leading to formal adoption by the second IPBES Plenary (IPBES/2/4), and therefore represents a key foundation for all IPBES activities. The framework recognizes different knowledge systems, including indigenous and local knowledge (ILK) systems, which can be complementary to those based on science (see chapter 1 for detailed description).

IUCN Red List
The IUCN Red List is an indicator of the health of biodiversity. It provides taxonomic, conservation status and distribution information on plants, fungi and animals that have been globally evaluated using the IUCN Red List Categories and Criteria. This system is designed to determine the relative risk of extinction, and the main purpose of the IUCN Red List is to catalogue and highlight those plants and animals that are facing a higher risk of global extinction (IUCN, 2012b).

J

Jevons paradox
See 'Rebound effect'.

Joint production
See 'Co-production'.

K

Key Biodiversity Areas (KBAs)
Sites contributing significantly to the global persistence of biodiversity. They represent the most important sites for biodiversity conservation worldwide, and are identified nationally using globally standardized criteria and thresholds (UNEP-WCMC, 2014).

Keystone species
A species whose impact on the community or ecosystem is disproportionately large relative to its abundance. Effects can be produced by consumption (trophic interactions), competition, mutualism, dispersal, pollination, disease, or habitat modification (nontrophic interactions) (Millenium Ecosystem Assessment, 2005).

L

Land cover
The physical coverage of land, usually expressed in terms of vegetation cover or lack of it. Related to, but not synonymous with, land use (Millenium Ecosystem Assessment, 2005).

Land degradation
Refers to the many processes that drive the decline or loss in biodiversity, ecosystem functions or their benefits to people and includes the degradation of all terrestrial ecosystems. See 'Habitat degradation'.

Land grabbing
See 'Large-scale land acquisition'.

Land sharing and sparing
Concepts used to describe, in general terms, spatial-temporal arrangements of agricultural and non-agricultural areas. Land sharing is a situation where farming practices enable biodiversity to be maintained within agricultural landscapes. Land sparing, also called "land separation" involves restoring or creating non-farmland habitat in agricultural landscapes at the expense of field-level agricultural production - for example, woodland, natural grassland, wetland, and meadow on arable land. This approach does not necessarily imply high-yield farming of the non-restored, remaining agricultural land (Rey Benayas & Bullock, 2012). See also 'Conservation agriculture'.

Land use
The human use of a piece of land for a certain purpose (such as irrigated agriculture or recreation or conservation). Influenced by, but not synonymous with, land cover (Millenium Ecosystem Assessment, 2005). Land-use change refers to a change in the use or management of land by humans, which may lead to a change in land cover.

Land use intensification
Activities undertaken with the intention of enhancing the productivity or profitability per unit area of land use, such as in agriculture, including intensification of particular land uses as well as changes between land uses (Martin *et al.*, 2018).

Landrace
A breed that has largely developed through adaptation to the natural environment and traditional production system in which it has been raised (FAO, 2013).

Landscape
An area of land that contains a mosaic of ecosystems, including human-dominated ecosystems.

Landscape functioning
The capacity or potential of landscapes to maintain ecosystem functions and to provide services (adapted from Bolliger & Kienast, 2010).

Landscape heterogeneity
Landscape heterogeneity is a complex phenomenon involving the size, shape and composition of different landscape units and the spatial (and temporal) relations between them, such as between different land cover types (Cale & Hobbs, 1994).

Large-scale land acquisition (LSLA)
The control (whether through ownership, lease, concession, contracts, quotas, or general power) of larger than locally-typical amounts of land by any persons or entities (public or private, foreign or domestic) via any means ('legal' or 'illegal') for purposes of speculation, extraction, resource control or commodification usually at the expense of local ownership and access, agroecological principles, customary forms of land stewardship, and affecting food sovereignty and human rights (adapted from Baker-Smith & Miklos-Attila, 2016). It is sometimes also called "land grabbing".

Law of the Sea
The United Nations Convention on the Law of the Sea (UNCLOS), in force since 1994, defines the rights and obligations of nations (167 at present) with regard to the use of the world's oceans and their resources, and the protection of the marine and coastal environment. The UNCLOS also defines national marine jurisdiction on maritime territories and provides guidelines related to the use and management of marine environment and resources.

Leaf Area Index (LAI)
The total area of green leaves per unit area of ground covered (FAO, 2018a).

Leakage effect
Phenomena whereby the reduction in emissions (relative to a baseline) in a

jurisdiction/sector associated with the implementation of mitigation policy is offset to some degree by an increase outside the jurisdiction/sector through induced changes in consumption, production, prices, land use and/or trade across the jurisdictions/sectors. Leakage can occur at a number of levels, be it a project, state, province, nation or world region (IPCC, 2014a).

Learning (traditional and formal)
Learning refers to the process of knowledge and skills acquisition. Studies on learning have payed attention to the different ways people acquire knowledge, practices, and beliefs (i.e., imitation, copying, trial-and-error), but also to the dynamics of knowledge transmission, or the different sources from which knowledge, practices, and beliefs are passed from one individual to another (i.e., from parents, peers, teachers, prestigious peoples, media, etc). Social learning is defined as the acquisition of new information by observing and emulating others, and it is a key human strategy that allows for the accumulation of culturally transmitted knowledge (Boyd & Richerson, 2005; Boyd & Silk, 2014).

M

Macroecology
A subfield of ecology that deals with the study of relationships between organisms and their environment at large spatial scales, and involves characterizing and explaining statistical patterns of abundance, distribution and diversity (Blackburn & Gaston, 2002).

Maladaptation
A trait that is, or has become, more harmful than helpful, in contrast with an adaptation, which is more helpful than harmful (Barnett & O'Neill, 2010).

Malnutrition
Malnutrition refers to deficiencies, excesses or imbalances in a person's intake of energy and/or nutrients. The term malnutrition covers 2 broad groups of conditions. One is 'undernutrition'—which includes stunting (low height for age), wasting (low weight for height), underweight (low weight for age) and micronutrient deficiencies or insufficiencies (a lack of important vitamins and minerals). The other is overweight, obesity and diet-related noncommunicable diseases (such as heart disease, stroke, diabetes and cancer) (WHO, 2016).

Marginal lands
Land having limitations which in aggregate are severe for sustained application of a given use. On these lands, options are limited for diversification without the use of inputs; inappropriate management of lands may cause irreversible degradation (CGIAR, 1999).

Marginalization
Marginalization refers to the set of processes through which some individuals and groups face systematic disadvantages in their interactions with dominant social, political and economic institutions. The disadvantages arise from class status, social group identity (kinship, ethnicity, caste and race categories), political affiliation, gender, age and disability (Institute of Development and Economic Alternatives, 2016).

Mariculture
A branch of aquaculture involving the culture of organisms in a medium or environment which may be completely marine (sea), or sea water mixed to various degrees with fresh water, including brackishwater areas (Sivalingam, 1981).

Mechanistic modelling
A model with hypothesized relationship between the variables in the dataset where the nature of the relationship is specified in terms of the biological processes that are thought to have given rise to the data.

Megadiverse country
Countries (17) which have been identified as the most biodiversity-rich countries of the world, with a particular focus on endemic biodiversity (UNEP-WCMC, 2014).

Mesic areas
Synonym for moist areas (IUCN, 2012a).

Meta-analysis
A quantitative statistical analysis of several separate but similar experiments or studies in order to test the pooled data for statistical significance.

Metabolic activity
Chemical transformations that sustain life at the cell level.

Microevolution
A change in gene frequency within a population. Evolution at this scale can be observed over short periods of time — for example, between one generation and the next, the frequency of a gene for pesticide resistance in a population of crop pests increases. Such a change might come about because natural selection favored the gene, because the population received new immigrants carrying the gene, because some nonresistant genes mutated to the resistant version, or because of random genetic drift from one generation to the next (University of California Museum of Paleontology, 2018b).

Micro-habitats
The small-scale physical requirements of a particular organism or population.

Micronutrients
Substances that are only needed in very small amounts but essential to organisms to produce enzymes, hormones and other substances fundamental for proper growth and development (WHO, 2015).

Microparticles
Particles with dimensions between 0.1 and 100 micrometers, e.g., pollen, sand, dust (Vert *et al.*, 2012).

Micro-plastics
Plastic debris that are less than five millimeters in length (NOAA, 2018a).

Minimum tillage
Minimum tillage systems are tillage systems in which the ground is worked very little before the seed is sown, and where crops can be sown almost immediately after the previous crop has been harvested (Rawson & Gómez Macpherson, 2000).

Moisture recycling
The contribution of local evaporation and evapotranspiration to local precipitation (Trenberth & Trenberth, 1999).

Monitoring
The repeated observation of a system in order to detect signs of change in relation to a predetermined or expected standard.

Monoculture
The agricultural practice of cultivating a single crop over a whole farm or area (FAO, 2001b).

Monophyletic
The condition in which a group of taxa share a common ancestry, being the entire set of evolutionary descendants from a common ancestor.

Mother Earth
An expression used in a number of countries and regions to refer to the planet Earth and the entity that sustains all living things found in nature with which humans have an indivisible, interdependent physical and spiritual relationship (see ‘Nature’).

Mutualism
Interaction between two species that benefits the two species (Bronstein, 1994).

N

Nagoya protocol
The Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization (ABS) is a supplementary agreement to the 1992 Convention on Biological Diversity. It provides a transparent legal framework for the effective implementation of one of the three objectives of the CBD: the fair and equitable sharing of benefits arising out of the utilization of genetic resources, thereby contributing to the conservation and sustainable use of biodiversity. The Nagoya Protocol aims to create greater legal certainty and transparency for both providers and users of genetic resources by establishing more predictable conditions for access to genetic resources and helping to ensure benefit-sharing when genetic resources leave the country providing the genetic resources. The Nagoya Protocol on ABS was adopted on 29 October 2010 in Nagoya, Japan and entered into force on 12 October 2014.

National biodiversity strategies and action plans (NBSAPs)
The Convention on Biological Diversity calls on each of its Parties to prepare a National Biodiversity Strategy and Action Plan (Article 6a) that establishes specific activities and targets for achieving the objectives of the Convention. These plans mostly are implemented by a partnership of conservation organizations. Species or habitats which are the subject of NBSAPs are the governments stated priorities for action and therefore raise greater concern where they are threatened. NBSAPs do not carry legal status and listed species and habitat types are not necessarily protected (although some are covered by other legislation) (Hesselink *et al.*, 2007).

Natural capital
A concept referring to the stock of renewable and non-renewable natural resources (e.g., plants, animals, air, water, soils, minerals) that combine to yield a flow of benefits to people (UNDP, 2016b). Within the IPBES conceptual framework, it is part of the “nature” category, representing an economic-utilitarian perspective on nature, specifically those aspects of nature that people use (or anticipate to use) as source of NCP (see chapter 1).

Natural habitat
Areas composed of viable assemblages of plant and/or animal species of largely native origin and/or where human activity had not essentially modified an area’s primary ecological functions and species composition (UNEP-WCMC, 2014).

Natural heritage
Natural features, geological and physiographical formations and delineated areas that constitute the habitat of threatened species of animals and plants and natural sites of outstanding universal value from the point of view of science, conservation or natural beauty (UNESCO, 1972).

Nature
In the context of IPBES (also referred as “living nature”), it refers to the nonhuman world, including coproduced features, with particular emphasis on living organisms, their diversity, their interactions among themselves and with their abiotic environment. Within the framing of the natural sciences, nature include e.g., all dimensions of biodiversity, species, genotypes, populations, ecosystems, communities, biomes, Earth life support’s systems, and their associated ecological, evolutionary and biogeochemical processes. Within the framework of economics, it includes categories such as biotic natural resources, natural capital and natural assets. Within a wider context of social sciences and humanities and interdisciplinary environmental sciences, it is referred to with categories such as natural heritage, living environment, or the nonhuman. Within the framing of other knowledge systems, it includes categories such as Mother Earth (shared by many IPLC around the world; see ‘Mother Earth’), Pachamama (South American Andes), se¯nluo´-wa`nxia`ng and tien-ti (East Asia), Country (Australia) , fonua/vanua/whenua/ples (South Pacific Islands), Iwigara (Northern Mexico), Ixofijmogen (Southern Argentina and Chile), among many others. The degree to which humans are considered part of nature varies strongly across these categories. Many aspects of biocultural diversity are part of nature, while some others pertain more to nature’s contributions to people and anthropogenic assets (also see Chapter 1).

Nature-based solutions
Actions to protect, sustainably manage, and restore natural or modified ecosystems, that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits (Cohen-Shacham *et al.*, 2016).

Nature’s contributions to people (NCP)
Nature’s contributions to people (NCP) are all the contributions, both positive and negative, of living nature (i.e., all organisms, ecosystems, and their associated ecological and evolutionary processes) to people’s quality of life. Beneficial contributions include e.g., food provision, water purification, flood control, and artistic inspiration, whereas detrimental contributions include e.g., disease transmission and predation that damages people or their assets. NCP may be perceived as benefits or detriments depending on the cultural, temporal or spatial context (Díaz *et al.*, 2018). IPBES considers a gradient of approaches to NCP, ranging from a purely generalizing approach to a purely context-specific one. Within the generalizing approach, IPBES identifies 18 categories of NCP, organized in three partially overlapping groups:

- Material contributions are substances, objects or other material elements from nature that directly sustain people’s physical existence and material assets. They are typically physically consumed in the process of being experienced, for example when organisms are transformed into food, energy, or materials for clothing, shelter or ornamental purposes.
- Non-material contributions are nature’s effects on subjective or psychological aspects underpinning people’s quality of life, both individually and collectively. Examples include forests and coral reefs providing opportunities for recreation and inspiration, or particular organism (animals, plants, fungi) or habitat (mountains, lakes) being the basis of spiritual or social-cohesion experiences.
- Regulating contributions are functional and structural aspects of organisms and ecosystems that modify environmental conditions experienced by people, and/or regulate the generation of material and non-material contributions. Regulating contributions frequently affect quality of

life in indirect ways. For example, people directly enjoy useful or beautiful plants, but only indirectly the soil organisms that are essential for the supply of nutrients to such plants.
(see chapters 1 and 2.3 for detailed definitions)

NCP (potential)
The capacity of an ecosystem to provide NCP (see chapter 2.3).

NCP (realized)
The actual flow of NCP that humanity receives. Realized NCP typically depends not only on potential NCP but also anthropogenic assets (e.g., boats and fishing gear, or farm equipment), human labor, and institutions. Institutions can facilitate or prevent access to resources and are often important for determining whether or not potential NCP generates realized NCP (see chapter 2.3).

Neo-endemic taxa
Recently diverged taxa that are endemic because of lack of dispersal/migration out of their ancestral area, as opposed to paleo-endemic taxa that were perhaps more widespread in the past and are now restricted to a local region (Mishler *et al.*, 2014).

Net Primary Production (NPP)
The difference between how much CO_2 vegetation takes in during photosynthesis (gross primary production) minus how much CO_2 the plants release during respiration (NASA Earth Observatory, 2018). It corresponds to the increase in plant biomass or carbon of a unit of a landscape (IPCC, 2001).

Nexus
A perspective which emphasizes the inter-relatedness and interdependencies of ecosystem components and human uses, and their dynamics and fluxes across spatial scales and between compartments. Instead of just looking at individual components or a specific sector (e.g., water, energy, food), the functioning, productivity and management of a complex system is taken into consideration. In such complex systems there are trade-offs as well as facilitation and amplification between the different components. A nexus approach can help address synergies and trade-offs among multiple sectors and among various Sustainable Development Goals and biodiversity targets simultaneously (adapted from UNU-FLORES, 2018; also see Chapter 5).

Niche (ecological)
A species' position within an ecosystem. This definition includes both the abiotic and biotic conditions necessary for the species to be able to persist (e.g., temperature range, food sources) and its ecological role, function or "job" (Polechová & Storch, 2008).

Niche models
Also known as species distribution models, niche models predict the spatial distribution of a species as a function of environmental variables. They are often used to project the future distributions of species in response to climate change (Wiens *et al.*, 2009).

Nitrogen deposition
The nitrogen transferred from the atmosphere to the Earth's surface by the processes of wet deposition and dry deposition (IPCC, 2014a).

Nitrogen-fixing species
Plants, such as legumes, living in symbiosis with micro-organisms in their roots that can perform biological nitrogen fixation, i.e., convert atmospheric nitrogen (N2) to ammonia (NH3). Plants can then assimilate NH3 to produce biomolecules (Wagner, 2011).

Non-timber forest products (NTFPs)
Any biological resources found in forests other than timber, including fruits, fuel wood and small wood, nuts, seeds, oils, foliage, game animals, berries, medicinal plants, fish, spices, barks, and mushrooms, among others (Prasad, 1993).

NOX
A generic term for the nitrogen oxides most relevant for air pollution (NO and NO2) (Omidvarborna *et al.*, 2015).

Nutrient availability
Nutrients that can be extracted by plant roots, generally from the soil (Silver, 1994).

Nutrient cycling
The processes by which elements are extracted from their mineral, aquatic, or atmospheric sources or recycled from their organic forms, converting them to the ionic form in which biotic uptake occurs and ultimately returning them to the atmosphere, water, or soil (Millenium Ecosystem Assessment, 2005).

O

Ocean acidification
A reduction in the pH of the ocean over an extended period, typically decades or longer, which is caused primarily by uptake of carbon dioxide from the atmosphere, but can also be caused by other chemical additions or subtractions from the ocean. Anthropogenic ocean acidification refers to the component of pH reduction that is caused by human activity (IPCC, 2014a).

Oceanic gyre
Large system of rotating ocean currents. There are five major gyres: the North and South Pacific Subtropical Gyres, the North and South Atlantic Subtropical Gyres, and the Indian Ocean Subtropical Gyre (NOAA, 2018c).

Oceanic oxygen minimum zones (OMZs)
Oxygen-deficient layers in the ocean water column. OMZs correspond to subsurface oceanic zones reaching ultra-low values of O_2 concentration (Paulmier & Ruiz-Pino, 2008).

Old-growth forest
From an ecological point of view, old-growth forests are a stage of forest development characterized by large/old trees and structural complexity including live and dead trees, and vertical and horizontal heterogeneity (including a multi-layered canopy). The structural diversity of old growth forests often supports distinctive/specialist biodiversity; large/old trees are keystone components of the ecosystem (Lindenmayer *et al.*, 2012).
In addition, the long-period of forest development without stand replacement disturbance allows many poor-dispersing species to accumulate (IUFRO, 2018). Other definitions can be found based on economic and social perspectives (Hilbert & Wienscczyk, 2007).

Oligotrophic
Nutrient-poor environment (IUCN, 2012a).

Ontology
The philosophical study of the nature of being, becoming, existence, or reality, as well as the basic categories of beings and their relations.

Open Ocean Pelagic Systems (OOPS)
Marine ecosystems in the light-flooded (euphotic) zone.

Organic agriculture
Any system that emphasizes the use of techniques such as crop rotation, compost or manure application, and biological pest control in preference to synthetic inputs. Most certified organic farming schemes prohibit all genetically modified organisms and almost all synthetic inputs. Its origins are in a holistic management system that avoids off-farm inputs, but some organic agriculture now uses relatively high levels of off-farm inputs. Recognition and certification of organic agriculture may vary significantly across countries.

Other Effective Area-based Conservation Measures (OECM)
A geographically defined area other than a protected area, which is governed and managed in ways that achieve positive and sustained long-term outcomes for the *in situ* conservation of biodiversity (CBD, 2018a).

Overexploitation
Overexploitation means harvesting species from the wild at rates faster than natural populations can recover. Includes overfishing, and overgrazing.

P

Paired catchment
Paired catchment studies have been widely used to assess the likely impact of land use change on water yield around the world. Such studies involve the use of two catchments (drainage basins) with similar characteristics in terms of slope, aspect, soils, area, precipitation and vegetation located adjacent to each other. Following a calibration period, where both catchments are monitored, one of the catchments is subjected to treatment and the other remains as a control. This allows the climatic variability to be accounted for in the analysis. The change in water yield can then be attributed to changes in vegetation. The paired catchment studies reported in the literature can be divided into four broad categories: (i) afforestation experiments; (ii) regrowth experiments; (iii) deforestation experiments; and (iv) forest conversion experiments (Best *et al.*, 2003).

Palma ratio
The share of all income received by the 10% people with highest disposable income divided by the share of all income received by the 40% people with the lowest disposable income (OECD, 2018b).

Participatory methods
Participatory research methods are a variety of qualitative and quantitative methods "geared towards planning and conducting the research process with those people whose life-world and meaningful actions are under study" (Bergold & Thomas, 2012). Participatory methods acknowledge the possibility, the significance, and the usefulness of involving research partners in the knowledge-production process (Bergold, 2007).

Participatory process
Specific methods employed to achieve active participation by all members of a group in a decision-making process (Chatty *et al.*, 2003).

Particulate matter (PM)
A mixture of suspended solid particles and liquid droplets (dust, dirt, soot, or smoke) found in the air (US Environmental Protection Agency, 2018c); also referred to as particulate pollution.

Particulate organic carbon (POC)
The carbon content of particulate organic matter (Fiedler *et al.*, 2008).

Particulate organic matter
The large fraction (usually more than 7 micrometers) of soil organic matter (Fiedler *et al.*, 2008).

Pathways
In the context of the IPBES global assessment, trajectories toward the achievement of goals and targets for biodiversity conservation, the management of nature and nature's contributions to people, and, more broadly, the UN 2030 Sustainable Development Goals.

Patrimonial species
A rare or threatened species which needs local management and which may be a flagship species and may have cultural importance (Pervanchon, 2004).

Payments for ecosystem services (PES)
Payments for ecosystem services (PES) is a term used to describe a process whereas a beneficiary or user of an ecosystem service makes a direct or indirect payment to a provider of that service. PES involve a series of payments to land or other natural resource owners in return for a guaranteed flow of ecosystem services or certain actions likely to enhance their provision over-¬and-above what would otherwise be provided in the absence of payment (UNDP, 2018).

Peatland
Wetlands which accumulate organic plant matter *in situ* because waterlogging prevents aerobic decomposition and the much slower rate of the resulting anaerobic decay is exceeded by the rate of accumulation.

Pelagic
Occurring or living in open waters or near the surface with little contact with or dependency on the bottom (IUCN, 2012a).

People and Plants initiative
A collaboration initiated in 1992 between the World-Wide Fund for Nature (WWF), UNESCO-MAB and the Royal Botanic Gardens Kew on the promotion of ethnobotany and the equitable and sustainable use of plant resources.

Permafrost
Ground (soil or rock and included ice and organic material) that remains at or below 0°C for at least two consecutive years (IPCC, 2014a).

Persistent organic pollutants (POPs)
Organic compounds that are resistant to environmental degradation through chemical, biological, and photolytic processes. POPs persist in the environment for long periods, are capable of long-range transport, bioaccumulate in human and animal tissue and biomagnify in food chains, and have potentially significant impacts on human health and the environment. Exposure to POPs can cause serious health problems including certain cancers, birth defects, dysfunctional immune and reproductive systems, greater susceptibility to disease and even diminished intelligence (Stockholm Convention Secretariat, 2017).

Phenological shifts
Changes in species phenology, mostly as a result of climate change (Scranton & Amarasekare, 2017).

Phenology
The study of the relationship between climate and the timing of periodic natural phenomena such as migration of birds, bud bursting, or flowering of plants (IUCN, 2012a).

Phenotype
The characteristics of an individual resulting from interaction between its genotype (genetic constitution) and its environment (IUCN, 2012a). These characteristics often

include behaviour, physiology (e.g., oxygen consumption, heart rate), life history (e.g., body size, age, offspring number), or morphology (e.g., body proportions).

Phenotypic attributes (biodiversity)
A distinct variant of a phenotypic characteristic of an organism; it may be either inherited or determined environmentally, but typically occurs as a combination of the two (Lawrence, 2005).

Phenotypic plasticity
The capacity of a single genotype to exhibit a range of phenotypes in response to variation in the environment (Whitman & Agrawal, 2009).

Phylogenetic diversity
Although species richness is a commonly used measure of biodiversity, it fails to capture the reality that species without close relatives contribute more uniqueness than do species with many close relatives. Phylogenetic diversity is used as a general term for a range of measures that consider the total length of all the branches linking a set of species on their phylogeny ("evolutionary tree") and so reflect species' evolutionary uniqueness. One of the first such measures (Faith, 1992) is simply the sum of the branch lengths.

Phylum
A major taxonomic grouping of animals linked by having a similar general body plan and thought to be a clade. In plants the similar category is called a division (Lawrence, 2005).

Plankton
Aquatic organisms that drift or swim weakly. Phytoplankton are the plant forms of plankton (e.g., diatoms), and are the dominant plants in the sea. Zooplankton are the animal forms of plankton. Picoplankton are all forms of plankton which size is comprised between 0.2 and 2 micrometers (mostly bacteria) (Mullin, 2001).

Poaching
Animal killing or trapping without the approval of the people who controls or own the land (Survival International, 2018).

Pollination
The transfer of pollen from an anther to a stigma. Pollination may occur within flowers of the same plant, between flowers of the same plant, or between flowers of different plants (or combinations thereof) (IPBES, 2016).

Polycentric governance
An organizational structure where multiple independent actors mutually order their relationships with one another under a general system of rules. There are different types of polycentric governance arrangements. (Ostrom, 2010).

Polyphyletic taxon
A group composed of a collection of organisms in which the most recent common ancestor of all the included organisms is not included, usually because the common ancestor lacks the characteristics of the group. Polyphyletic taxa are considered "unnatural", and usually are reclassified once they are discovered to be polyphyletic (University of California Museum of Paleontology, 2009).

Population bottleneck
A decrease in the gene pool of the population due to an event that drastically reduces the size of that population, such as an environmental disaster, the hunting of a species to the point of extinction, or habitat destruction that results in the deaths of organisms. Due to the event, many alleles, or gene variants, that were present in the original population are lost and the remaining population has a very low level of genetic diversity (Nature, 2017).

Population genetic structure
The total genetic diversity and its distribution within and among a set of populations. It is shaped by many factors, including life history, population size, geographical or environmental barriers, gene flow, selection and population crashes or bottlenecks (Gilleard & Redman, 2016).

Pore-water pressure
The pressure exerted by a fluid phase in a porous medium (soil or rock) composed of a solid framework and pores filled or partially filled with water or other fluid (Reid, 2013).

Poverty
Poverty is, at the most basic level, a state of economic deprivation. Its manifestations include hunger and malnutrition, limited access to education and other basic services. Other corollaries of poverty are social discrimination and exclusion as well as the lack of participation in decision-making.

Primary vegetation
Vegetation in a particular plant assemblage that has not been subject to human disturbance, or has been so little affected that its natural structure, functions and dynamics have not undergone any change that exceed the elastic capacity of the ecosystem (IUCN, 2012a).

Prior, informed consent (PIC)
See 'Free, prior and informed consent (FPIC)'.

Private deforestation (see deforestation)
Deforestation occurring on private lands.

Protected area
A protected area is a clearly defined geographical space, recognized, dedicated and managed, through legal or other effective means, to achieve the long-term conservation of nature with associated values to people. There are multiple categories of protected areas, including and excluding people from within its boundaries.

Protected Area Downgrading, Downsizing and Degazettement (PADDD)
Refers to legal changes that ease restrictions on the use of a protected area, shrink a protected area's boundaries or eliminate legal protections entirely (Mascia & Pailler, 2011).

R

Reactive nitrogen
All biologically, photochemically, and/or radiatively active forms of nitrogen; a diverse pool of nitrogenous compounds that includes organic compounds (e.g., urea, amines, proteins, amides), mineral nitrogen forms, such as nitrates and ammonium, as well as gases that are chemically active in the troposphere (NOx, ammonia, nitrous oxide) and contribute to air pollution and the greenhouse effect (FAO, 2018a).

Rebound effect
The pattern by which resource users tend to compensate for improved efficiency by shifting behaviour towards greater consumption, which undermines apparent gains. For example, an increased fuel saving of motor vehicle tends to be compensated by spending more money on other resources or by driving more (Alcott, 2005).

Recruitment (species)
The influx of new members into a population by reproduction or immigration (IUCN, 2012a).

REDD+
(Reducing emissions from deforestation and forest degradation)
Mechanism developed by Parties to the United Nations Framework Convention on Climate Change (UNFCCC), which creates a financial value for the carbon stored in forests by offering incentives for developing countries to reduce emissions from forested lands and invest in low-carbon paths to sustainable development. Developing countries would receive results-based payments for results-based actions. REDD+ goes beyond simply deforestation and forest degradation, and includes the role of conservation, sustainable management of forests and enhancement of forest carbon stocks.

Reduced impact logging (RIL)
The intensively planned and carefully controlled implementation of timber harvesting operations to minimize the environmental impact on forest stands and soils (FAO, 2018a).

Reforestation
Planting of forests on lands that have previously contained forests but that have been converted to some other use (IPCC, 2014a).

Regime
A long-term qualitative behaviour where the system's dynamics tend to stabilize, at different spatial and temporal scales in marine, terrestrial and polar systems (Rocha *et al.*, 2015).

Regime shift
Substantial reorganization in system structure, functions and feedbacks that often occurs abruptly and persists over time.

Remediation
Any action taken to rehabilitate ecosystems after their degradation.

Remote sensing
Methods for gathering data from a distance. In environmental studies and in monitoring, it usually refers to the use of satellite or airborne sensors to examine conditions and changes over large regions or landscape-scale analysis; often used in conjunction with Geographic Information Systems and often involves validation through on-the-ground activities (adapted from IUCN, 2012a).

Representation concentration pathways (RCPs)
Scenarios that include time series of emissions and concentrations of the full suite of greenhouse gases (GHGs) and aerosols and chemically active gases, as well as land use/land cover (IPCC, 2014a).

Resilience
The capacity of a system to absorb disturbance and reorganize while undergoing change so as to still retain essentially the same function, structure, identity, and feedbacks (Walker *et al.*, 2004). A concept initially developed and applied in ecology, which progressively gained usage in the social and environmental sciences.

Restoration
Any intentional activities that initiates or accelerates the recovery of an ecosystem from a degraded state.

Re-wilding
The preservation of land with the goal of restoring natural ecosystem processes and reducing human control of landscapes (Gillson *et al.*, 2011) to allow declining populations to rebound.

Richness (biodiversity)
The number of distinct biological entities (typically species, but also genotypes, taxonomic genera or families, etc.) within a given sample, community, or area (Millenium Ecosystem Assessment, 2005).

S

Sacred groves
A particular type of sacred natural sites represented, for instance, by patches of forest revered as sacred (Bhagwat & Rutte, 2006). Sacred groves may be revered e.g., as burial grounds (Mgumia & Oba, 2003) or sites of ancestral or deity worship (Ramakrishnan *et al.*, 1998). There are locally-established rules that regulate how sacred groves can be used (Hughes & Chandran, 1998). Observation of those rules often contributes to the biodiversity conservation on those sites (Bhagwat & Rutte, 2006).

Sacred natural sites (SNS)
Areas of land or water that have special spiritual significance to peoples and communities (Verschuuren *et al.*, 2010). They consist of natural features, ranging from entire ecosystems, such as mountains, forests or islands, to single natural features such as a tree, spring or boulder, and are very important for the conservation of nature and culture. Sacred natural sites have been managed based on indigenous and local knowledge systems, developed over long periods of time, and are source of cultural identity.

Salinization
The process of increasing the salt content in soil is known as salinization. Salinization can be caused by natural processes such as mineral weathering or by the gradual withdrawal of an ocean. It can also come about through artificial processes such as irrigation.

Sea ice
Any form of ice found at sea which has originated from the freezing of sea water (sea ice does not include superstructure icing). Ice formed from the freezing of the waters of the Great Lakes will be considered the same as sea ice (NOAA's National Weather Service, 2009).

Seascape
The marine equivalent to landscape, which describes marine and coastal ecosystems defined primarily by their biological and environmental structure but also by ecosystem functioning, e.g., reefs shaped by corals living in symbiosis with microalgae and associated to a rich additional fauna comprising invertebrates and fish.

Second-growth forest
Regenerating forest after disturbance, such as fire or clear-cutting (IUCN, 2012a).

Sedimentary upper slope
Refers to the upper part of continental slopes. See 'Continental slope'.

Selection pressure
The effect of any feature of the environment that results in natural selection, e.g., food shortage, predator activity, competition from members of the same or other species (Lawrence, 2005).

Semi-natural habitats
An ecosystem with most of its processes and biodiversity intact, though altered by human activity in strength or abundance relative to the natural state.

Sense of place
Characteristics that make a place special or unique, as well as to those that foster a sense of authentic human attachment and belonging (Casey, 2001).

Sessile
Attached or stationary, as opposed to free-living or motile (Lawrence, 2005).

Shale gas
Natural gas from shale formations (European Commission, 2018).

Shamanism
A system that links people to the vital forces of nature, especially the soul or inner-self of non-humans or nature spirits, through the mediation of a specialist, the shaman. Shamans are generally trained through enduring experiences including the consumption of psychotropic substances that lead them to experience spiritual connections that are mobilized to combat illness and any dangers that may affect their community.

Shared socio-economic pathways (SSPs)
Shared Socio-economic Pathways (SSPs) describe alternative socio-economic futures in the absence of climate policy intervention, comprising sustainable development (SSP1), regional rivalry (SSP3), inequality (SSP4), fossil–fuelled development (SSP5) and middle-of-the-road development (SSP2). The combination of SSP-based socio-economic scenarios and Representative Concentration Pathway (RCP)-based climate projections provides an integrative frame for climate impact and policy analysis (IPCC, 2018).

Shelf ecosystems
See 'Continental shelf'.

Shifting cultivation
An agricultural system in which plots of land are cultivated temporarily, then abandoned to regenerate soil fertility by the regeneration of natural vegetation; the system can continue to produce food and materials even after abandoned. The system involves 1) the removal of the natural vegetation (usually forest or shrub land) in most cases (though not exclusively) by cutting and subsequent burning, mulching, or their combinations (such as in slash-and-burn, slash-and-mulch); 2) an alternation between a short duration of cultivation and a comparatively long duration of bush or forest fallow (such as in swidden agroforestry); and 3) the regular, in most cases cyclical, shifting of field (Erni, 2015). Shifting cultivation systems are found around the world, particularly in tropical areas, in a wide range of soils and vegetation types, under a diversity of land and resource management, using different crops and cultivation methods, and are practiced by innumerous Indigenous Peoples and Local Communities (Heinimann *et al.*, 2017; Nye & Greenland, 1960).

Slash-and-burn agriculture
See 'Shifting cultivation'.

Small-scale or non-industrial fisheries
Traditional fishing performed by family and/or community units rather than commercial units, using a relatively small amount of capital and energy, and carrying out short fishing trips close to coasts and mainly for local consumption (FAO, 2018a).

Social capital
As used in the global assessment, social capital refers to networks together with shared norms, values and understandings that facilitate co-operation within or among groups. Put together, these networks and understandings engender trust and so enable people to work together (OECD, 2007a). The term is also used in other ways, such as to refer to assets facilitating the achievement and/or maintenance of individual and family goals and privileges (Brondizio, *et al.*, 2009).

Social network
A network of social interactions and personal relationships.

Social norms
A social norm is what people in a group generally agree as shared expectations guiding individual and collective behaviour and action, that is, believed to be a typical action, an appropriate action, or both, and without necessarily representing a formal rule (adapted from Mackie *et al.*, 2015).

Social welfare
The condition of a society emphasizing happiness and contentment; social welfare relates to how individuals use their relationships to other actors in societies for their own and for the collective good; it has both material elements and wider spiritual and social dimensions (Adger, 2003).

Socio-ecological production landscapes and seascapes (SEPLS)
Dynamic mosaics of habitats and land uses where the harmonious interaction between people and nature maintains biodiversity while providing humans with the goods and services needed for their livelihoods, survival and well-being in a sustainable manner (IPSI, 2018).

Social-ecological system
A concept used in a variety of analytical approaches intended to examine the mutual and interdependent relationship between people and nature as inter-linked, recognizing that humans should be seen as a part of, not apart from, nature (Berkes & Folke, 1998), and nature as inter-linked to social systems (Ostrom 2009).

Soil compaction
An increase in density and a decline of porosity in a soil that impedes root penetration and movements of water and gases.

Soil degradation
An alteration of soil properties which cause negative effects on one or more soil functions, human health or the environment (ISO, 2013). Also see 'Habitat degradation' and 'Land degradation'.

Soil fertility
The capacity of a soil to receive, store and transmit energy to support plant growth. It is the component of overall soil productivity that deals with its available nutrient status, and its ability to provide nutrients out of its own reserves and through external applications for crop production (FAO, 2018c).

Soil organic matter (SOM)
Matter consisting of plant and/or animal organic materials, and the conversion products of those materials in soils (FAO & ITPS, 2015).

Species
An interbreeding group of organisms that is reproductively isolated from all other organisms, although there are many partial exceptions to this rule in particular taxa. Operationally, the term species is a generally agreed fundamental taxonomic unit, based on morphological or genetic similarity, that once described and accepted is associated with a unique scientific name (Millenium Ecosystem Assessment, 2005).

Species composition
The array of species in a specific sample, community, or area.

Species extirpation
The local extinction of a species.

Species traits
The morphological, physiological, phonological or behavioural characteristics of an organism, that typically inform about its response to the environment and effects

on the ecosystem (Lavorel & Garnier, 2002; Violle *et al.*, 2007).

Species-area relationship
A well-known strong empirical relationship between the area (A) of a region or patch of habitat and the number of species (S) it contains. Over most spatial scales, a power-law relationship S = cAz provides a good fit to data, with z often around 0.25 for separate sets of regions (known as the island species-area relationship) and 0.15 for nested parts of the same region (known as the continental species-area relationship). The species-area relationship has often been used to estimate the size of an extinction debt (qv) resulting from habitat loss (Rosenzweig, 1995).

Spillover effects/off-site effects
Human impacts or natural disturbances beyond system boundaries. These effects can be positive or negative, socioeconomic or/and environmental and can be much more profound than the effects within the focal system (Liu *et al.*, 2013).

Stability (social-ecological system)
The degree to which a system can continue to function if inputs, controls, or conditions are disrupted. It is a reflection of how minor a perturbation is capable of rendering the system inoperable or degraded; the types of perturbation to which the system is especially vulnerable; whether the system can "ignore" certain stresses; and the degree to which the system can be altered by surprise (Kerner & Thomas, 2014).

State (social-ecological system)
The collection of variables that describe the whole of the social–ecological system, including the attributes of ecosystem service providers and beneficiaries (Harrington *et al.*, 2010).

Stewardship practices
The responsible use and protection of the natural environment through conservation actions, active restoration and the sustainable use and management of resources (Bennett *et al.*, 2018).

Stratification (water column)
The formation of layers of water masses with different properties - salinity, oxygenation, density, temperature - that act as barriers to water mixing. These layers are normally arranged according to density, with the least dense water masses sitting above the more dense layers (Miller & Wheeler, 2012).

Subsistence agriculture
Farming system emphasizing production for use rather than for sale (FAO, 1998), but it may also involve some level of market-oriented production.

Succession (ecological)
The process whereby communities of plants, animals and microorganisms are replaced by others, usually more complex, over time as an area is colonized. Primary succession occurs on bare ground (e.g., after a volcanic eruption); secondary succession follows the interruption of a primary succession, e.g., after disturbances such as logging, ploughing or burning (Lawrence, 2005).

Sustainability
A characteristic or state whereby the needs of the present and local human population can be met without compromising the ability of future generations or populations in other locations to meet their needs (Millenium Ecosystem Assessment, 2005). There are multiple and complementary, and in cases conflicting, definitions of sustainability.

Sustainable community forestry
Forestry management strategies and practices designed to meet present needs of forest resource use without compromising the needs and options of future generations.

Sustainable development
Originally popularized by the UN report 'Our Common Future' (1987), it is intended to mean development that meets the needs and aspirations of the current generation without compromising the ability to meet those of future generations (Hesselink *et al.*, 2007).

Sustainable use
The use of components of biological diversity in a way and at a rate that does not lead to the long-term decline of biological diversity, thereby maintaining its potential to meet the needs and aspirations of present and future generations (Convention on Biological Diversity, 1992)

Swidden agriculture
See 'Shifting cultivation'.

Symbiosis
A long-term interaction between two species that can often have mutual benefit for both species (IUCN, 2012a).

T

Taboo
A social or religious custom prohibiting or restricting a particular practice or forbidding association with a particular person, place, species or behavior.

Taxon / taxonomic group
A category applied to a group in a formal system of nomenclature, e.g., species, genus, family etc. (plural: taxa).

Taxonomic diversity
Variety of species or other taxonomic categories (IUCN, 2012a).

Telecoupling
Socioeconomic-environmental interactions over distances (Liu *et al.*, 2013). It is an umbrella concept that encompasses various types of distant interactions, such as international trade, tourism, migration, foreign investment, species invasion, payments for ecosystem services, water transfer, information dissemination, knowledge transfer, and technology transfer (Liu *et al.*, 2015). Another related term is 'teleconnection'.

Tele-grabbing
Transboundary acquisition of land.

Tenure security
An agreement between an individual or group to land, resources, and residential property, which is governed and regulated by a legal and administrative framework and that may include both customary and statutory systems (Payne & Durand-Lasserve, 2012).

Territorial use rights in fisheries (TURFs)
The restriction of access to, and use of, a particular fishing ground or site to a group or an individual. This group, usually small in size, can determine how to harvest fish from the site and to whom the fish is allocated (Ward *et al.*, 2004).

Threatened species
In the IUCN Red List terminology, a threatened species is any species listed in the Red List categories Critically Endangered, Endangered, or Vulnerable.

Tidal flats
Intertidal, non-vegetated, soft sediment habitats, found between mean high-water and mean low-water spring tide datums and generally located in estuaries and

other low energy marine environments (Dineen, 2010).

Timber line
The altitude (in mountains) and latitude above which trees are unable to grow — also called tree line (Lawrence, 2005).

Tipping point
A set of conditions of an ecological and/or social-ecological system where further perturbation will cause rapid change and prevent the system from returning to its former state.

Total allowable catch (TAC)
The total catch allowed to be taken from a resource within a specified time period (usually a year) by all operators; designated by the regulatory authority. Usually allocated in the form of quotas (IUCN, 2012a).

Totemism
A principle or an ontology found within societies that differentiate different sections of the society, according to the attachment of these sections to animal or plant tutelar and ancestral spirits. In other words, totemism defines discontinuities in social order according to each group's attachment to a specific animal or plant spirit that is perceived as having similar features to this section (or clan) and an innerself that also ressembles people in this section (and reciprocally).

Traditional and community-based management systems
Resource management strategies and practices based on accumulated indigenous and local knowledge acquired through community-based learning processes and transmitted between successive generations, and implemented through community-based institutional arrangements.

Traditional ecosystem healing principles
Restoration and ecosystem management activities based on indigenous and local knowledge and often executed by Indigenous Peoples and Local Communities to restore and maintain the healthy functioning of ecosystems.

Traditional farming
A term used to refer to complex, diverse and locally-adapted agricultural systems, managed with time-tested through multi-generational experimentation, as well as diffusion of knowledge and practices. While the term 'traditional' is used to refer to a persisting long-term farming system, it does not intend to imply that such systems are static (see Altieri & Koohafkan, 2008).

Transformability (part of resilience)
The capacity to cross thresholds, enter new development trajectories, abandon unsustainable actions and chart better pathways to established targets (Folke *et al.* 2010).

Transformative change
A fundamental, system-wide reorganization across technological, economic and social factors, including paradigms, goals and values (IPBES, 2018; IPCC, 2018).

Trophic level
The level in the food chain in which one group of organisms serves as a source of nutrition for another group of organisms (e.g., primary producers, primary or secondary consumers, decomposers).

Trophic transfer
The transport of contaminants between two trophic levels (Suedel *et al.*, 1994).

U

Units of Analysis
In the context of IPBES, a broad-based classification system of terrestrial, freshwater and marine systems at the global level, considering both the state of nature in classes equivalent to 'biomes', and classes where ecosystem structure and function have been severely altered through human management, which can be called 'anthropogenic biomes' or 'anthromes'. Seventeen units of analysis have been identified by IPBES to serve as a framework for comparison within and across assessments and represent a pragmatic solution. The IPBES units of analysis are not intended to be prescriptive for other purposes than those of IPBES assessments. They are likely to evolve as the work of IPBES develops (see chapter 1).

Upscaling
See 'Downscaling'.

Upwelling
A process in which deep, cold water rises toward the surface replacing warmer water pushed away by winds. Water that rises to the surface as a result of upwelling is typically colder and rich in nutrients, which "fertilize" surface waters, meaning that these surface waters often have high biological productivity (NOAA, 2018e).

Urban ecosystems
Any ecological system located within a city or other densely settled area or, in a broader sense, the greater ecological system that makes up an entire metropolitan area (Pickett, 2015).

Urban metabolism
A method to evaluate the flows of energy and materials within an urban system, which can provide insights into the system's sustainability and the severity of urban problems such as the impact of excessive social, community, and household metabolism at scales ranging from global to local (Zhang *et al.*, 2015).

Urbanization
The increase in the proportion of a population living in urban areas; the process by which a large number of people becomes permanently concentrated in relatively small areas, forming cities (OECD, 2001c).

V

Values
- **Value systems:** Set of values according to which people, societies and organizations regulate their behaviour. Value systems can be identified in both individuals and social groups (Pascual *et al.*, 2017).
- **Value (as principle):** A value can be a principle or core belief underpinning rules and moral judgments. Values as principles vary from one culture to another and also between individuals and groups (IPBES/4/INF/13).
- **Value (as preference):** A value can be the preference someone has for something or for a particular state of the world. Preference involves the act of making comparisons, either explicitly or implicitly. Preference refers to the importance attributed to one entity relative to another one (IPBES/4/INF/13).
- **Value (as importance):** A value can be the importance of something for itself or for others, now or in the future, close by or at a distance. This importance can be considered in three broad classes. 1. The importance that something has subjectively, and may be based on experience. 2. The importance that something has in meeting objective needs. 3. The intrinsic value of something (IPBES/4/INF/13).
- **Value (as measure):** A value can be a measure. In the biophysical sciences,

any quantified measure can be seen as a value (IPBES/4/INF/13).

- **Non-anthropocentric value:** A non-anthropocentric value is a value centered on something other than human beings. These values can be non-instrumental or instrumental to non-human ends (IPBES/4/INF/13).
- **Intrinsic value:** This concept refers to inherent value, that is the value something has independent of any human experience or evaluation. Such a value is viewed as an inherent property of the entity and not ascribed or generated by external valuing agents (Pascual *et al.*, 2017).
- **Anthropocentric value:** The value that something has for human beings and human purposes (Pascual *et al.*, 2017).
- **Instrumental value:** The value attributed to something as a means to achieving a particular end (Pascual *et al.*, 2017).
- **Non-instrumental value:** The value attributed to something as an end in itself, regardless of its utility for other ends.
- **Relational value:** The values that contribute to desirable relationships, such as those among people or societies, and between people and nature, as in "Living in harmony with nature" (IPBES/4/INF/13).
- **Integrated valuation:** The process of collecting, synthesizing, and communicating knowledge about the ways in which people ascribe importance and meaning of nature's contributions to humans, to facilitate deliberation and agreement for decision making and planning (Pascual *et al.*, 2017).

(see chapter 1 for more details)

W

Water footprint
The water footprint measures the amount of water used to produce each of the goods and services we use. It can be measured for a single process, such as growing rice, for a product, such as a pair of jeans, for the fuel we put in our car, or for an entire multi-national company. The water footprint can also tell us how much water is being consumed by a particular country – or globally – in a specific river basin or from an aquifer (Hoekstra *et al.*, 2011).

Water grabbing
A situation where powerful actors are able to take control of, or reallocate to their own benefits, water resources already used by local communities or feeding aquatic ecosystems on which their livelihoods are based (Mehta *et al.*, 2012).

Water stress
Water stress occurs in an organism when the demand for water exceeds the available amount during a certain period or when poor quality restricts its use (European Environment Agency, 2018).

Water use efficiency
The ratio between effective water use and actual water withdrawal. In irrigation, it represents the ratio between estimated plant water requirements (through evapotranspiration) and actual water withdrawal (FAO, 2018a).

Welfare
See 'Social welfare'.

Wellbeing (human)
A perspective on a good life that comprises access to basic resources, freedom and choice, health and physical, including psychological, well-being, good social relationships, security, equity, peace of mind and spiritual experience. Well-being is achieved when individuals and communities can act meaningfully to pursue their goals and can enjoy a good quality of life. The concept of human well-being is used by many countries and societies. In the context of IPBES' conceptual framework, it is used complementary and together with living in harmony with nature, and living well in balance and harmony with Mother Earth. All these are different perspectives on a good quality of life (see chapter 1).

Wetlands
In the context of IPBES, wetlands are permanent or temporary freshwater, brackish and marine areas (floodplains, bogs, swamps, marshes, estuaries, deltas, peatlands, potholes, vernal pools, fens and other types, depending on geography, soil, and plant life) where water covers the soil, or is present either at or near the surface of the soil all year or for varying periods of time during the year. A division was made between inland waters (lakes, rivers, reservoirs) and wetlands.

Wild habitat
See 'Natural habitat'.

Wild relative
Wild species related to crops, including crop progenitors (FAO, 2018a).

Wilderness
Ecosystems, landscapes and seascapes with a very low degree of human influence, at present with full recognition that they are often inhabited and managed by people, and have been so for centuries or millennia, often at low population densities, and therefore their native biodiversity and ecological and evolutionary processes have not been reconfigured by human drivers to a significant degree (Kormos *et al.*, 2017; Potapov *et al.*, 2017; Watson *et al.*, 2016). Not all areas designated as wilderness conform to this definition, especially in Europe where abandoned agricultural areas 'managed' by 'wild living' large herbivores are also called wilderness. Some wilderness areas in the world show transition to cultural landscapes with low human influence.

Willingness-to-accept
Estimate of the amount people are prepared to accept in exchange for a certain state or good (e.g., WTA for protection of an endangered species) (IUCN, 2012a).

Willingness-to-pay
Estimate of the amount people are prepared to pay in exchange for a certain state or good (e.g., WTP for protection of an endangered species) (IUCN, 2012a).

Worldviews
Worldviews are defined by the connections between networks of concepts and systems of knowledge, values, norms and beliefs. Individual person's worldviews are molded by the community(ies) the person belongs to. Practices are embedded in worldviews and are intrinsically part of them, such as through rituals, institutional regimes, social organization, but also in environmental policies, in development choices, among others.

Z

Zoonotic disease
Zoonotic disease or zoonoses are directly transmitted from animals to humans via various routes of transmission (e.g., air - influenza; bites and saliva - rabies).

ANNEX II
Acronyms

ABNJ	Area Beyond National Jurisdiction
ABS	Access and Benefit Sharing
AIDS	Acquired Immune Deficiency Syndrome
BaU	Business as Usual
BECCS	Bioenergy in combination with Carbon Capture and Storage
BII	Biodiversity Intactness Index
BOD	Biochemical Oxygen Demand
BVOC	Biogenic Volatile Organic Compounds
CAFF	Conservation for the Arctic Flora and Fauna
CAML	Census of Antarctic Marine Life
CBD	Convention on Biological Diversity
CBI	City Biodiversity Index
CCAMLR	Convention on the Conservation of Antarctic Marine Living Resources
CCRF	Code of Conduct for Responsible Fisheries (FAO)
CCS	Carbon Capture and Storage
CEMP	CCAMLR Ecosystem Monitoring Program
CFC	Chlorofluorocarbon
CH_4	Methane
CITES	Convention on International Trade in Endangered Species of Wild Fauna and Flora
CMS	Convention on the Conservation of Migratory Species of Wild Animals
CO_2	Carbon dioxide
COP	Conference of parties
CR	Critically Endangered (IUCN category)
CSR	Corporate Social Responsibilty
CWR	Crop Wild Relatives
DALY	Disability Adjusted Life-Year
DD	Data Deficient (IUCN category)
DDT	Dichlorodiphenyltrichloroethane
DGVM	Dynamic Global Vegetation Model
DMC	Domestic Material Consumption
DRC	Democratic Republic of Congo
EBSA	Ecologically or Biologically Significant Area
EBV	Essential Biodiversity Variables
EEZ	Exclusive Economic Zone
EIA	Environmental Impact Assessment
EJ	Exajoules
EKC	Environmental Kuznets Curve
EMRIP	Expert Mechanism on the Rights of Indigenous Peoples
EN	Endangered (IUCN category)
EPI	Environmental Performance Index
ESA	European Space Agency
ESH	Extent of Suitable Habitat
ESM	Earth System Model
ET	Evapotranspiration
EU	European Union
EVD	Ebola Virus Disease
EW	Extinct in the Wild (IUCN category)
FAO	Food and Agriculture Organization
FLEGT	Forest Law Enforcement, Governance and Trade (EU)
FPIC	Free, Prior and Informed Consent
FSC	Forest Stewardship Council
GA	Global Assessment
GBIF	Global Biodiversity Information Facility
GBA	Global Biodiversity Assessment
GBO	Global Biodiversity Outlook
GDP	Gross Domestic Product
GEF	Global Environment Facility
GEO	Global Environmental Outlook
GEO BON	Group on Earth Observations Biodiversity Observation Network
GHa	Gigahectares
GHG	Green House Gases
GIS	Geographic Information System
GMO	Genetically Modified Organism
GQL	Good Quality of Life
GtC	Gigatons of Carbon
GW	Gigawatts
HAB	Harmful Algal Bloom
HANPP	Human Appropriation of Net Primary Production
HDI	Human Development Index
HFC	Hydrofluorocarbon
HIV	Human Immunodeficiency Virus
IAMs	Integrated Assessment Models
IAS	Invasive Alien Species
IBA	Important Bird and Biodiversity Area
IBP	International Biological Program
ICCA	Indigenous Peoples and Community Conserved Territories and Areas

ANNEX III
List of authors and review editors

Co-chairs

Eduardo S. Brondízio
Chair
Department of Anthropology at Indiana University
United States of America

Sandra Díaz
Chair
CONICET - Universidad Nacional de Cordoba
Argentina

Josef Settele
Chair
Helmholtz Centre for Environmental Research – UFZ
Germany

Chapter 1

Eduardo S. Brondízio
Coordinating lead author
Department of Anthropology at Indiana University
United States of America

Sandra Díaz
Coordinating lead author
CONICET - Universidad Nacional de Cordoba
Argentina

Josef Settele
Coordinating lead author
Helmholtz Centre for Environmental Research – UFZ
Germany

Yildiz Aumeeruddy-Thomas
Lead author
Centre National de la Recherche Scientifique (CNRS)
France

Xuemei Bai
Lead author
Australian National University
Australia

Arne Geschke
Lead author
School of Physics, University of Sydney
Australia

Zsolt Molnár
Lead author
Centre for Ecological Research
Hungary

Aidin Niamir
Lead author
Senckenberg Society for Natural Research
Germany

Unai Pascual
Lead author
Basque Centre for Climate Change (BC3) and Ikerbasque, Basque Foundation for Science
Spain

Alan Simcock
Lead author
United Kingdom of Great Britain and Northern Ireland

Maria Manuela Carneiro Da Cunha
Review editor
The University of Chicago
United States of America

Georgina Mace
Review editor
University College London
United Kingdom of Great Britain and Northern Ireland

Harold Mooney
Review editor
Stanford University
United States of America

Pedro Jaureguiberry
Fellow
IMBIV (CONICET-Universidad Nacional de Córdoba)
Argentina

Chapter 2

Patricia Balvanera
Coordinating lead author
Instituto de Investigaciones en Ecosistemas y Sustentabilidad (IIES), Universidad Nacional Autónoma de México
Mexico

Kate A. Brauman
Coordinating lead author
University of Minnesota Institute on the Environment
United States of America

Lucas A. Garibaldi
Coordinating lead author
Universidad Nacional de Río Negro (UNRN)
Argentina

Kazuhito Ichii
Coordinating lead author
Chiba University
Japan

Zsolt Molnár
Coordinating lead author
Centre for Ecological Research
Hungary

David Obura
Coordinating lead author
Coastal Oceans Research and Development – Indian Ocean (CORDIO) East Africa
Kenya

Alexander Pfaff
Coordinating lead author
Duke University, Sanford School of Public Policy
United States of America

Stephen Polasky
Coordinating lead author
University of Minnesota
United States of America

Andy Purvis
Coordinating lead author
The Natural History Museum, London
United Kingdom of Great Britain and Northern Ireland

Katherine Willis
Coordinating lead author
Oxford University
United Kingdom of Great Britain and Northern Ireland

Cynthia Zayas
Coordinating lead author
University of the Philippines
Philippines

Yildiz Aumeeruddy-Thomas
Lead author
Centre National de la Recherce Scientifique (CNRS)
France

Nakul Chettri
Lead author
International Centre for Integrated Mountain Development (ICIMOD)
India

Fabrice Declerck
Lead author
Bioversity International/CGIAR
Belgium

Mohammad Ehsan Dulloo
Lead author
Consultative Group for International Agricultural Research (CGIAR)
Mauritius

Bardukh Gabrielyan
Lead author
Scientific Center of Zoology and Hydroecology
Armenia

Eduardo García Frapolli
Lead author
Universidad Nacional Autónoma de México
Mexico

Julian Gutt
Lead author
Alfred Wegener Institute Helmholtz Centre for Polar and Marine Research
Germany

Andrew Hendry
Lead author
McGill University
Canada

Syed Ainul Hussain
Lead author
Wildlife Institute of India
India

Ute Jacob
Lead author
Helmholtz Institute for Functional Marine Biodiversity, University of Oldenburg
Germany

Emre Keskin
Lead author
Ankara University
Turkey

Matías Mastrangelo
Lead author
National Research and Technology Council of Argentina (CONICET),
Universidad de Mar del Plata
Argentina

Leticia Merino
Lead author
National University of Mexico
Mexico

Peter Akong Minang
Lead author
World Agroforestry Centre (ICRAF)
Kenya

Nidhi Nagabhatla
Lead author
United Nations University (UNU-INWEH)
Institute for Water, Environment and Health
Canada

Aidin Niamir
Lead author
Senckenberg Society for Natural Research
Germany

Nsalambi Nkongolo
Lead author
Institut Facultaire des Sciences Agronomiques (IFA) de Yangambi, Kisangani,
Democratic Republic of Congo

Bayram Öztürk
Lead author
İstanbul University
Turkey

Hannes Palang
Lead author
Tallinn University, School of Humanities
Estonia

Pedro Henrique Santin Brancalion
Lead author
Universidade de São Paulo
Brazil

Lynne Shannon
Lead author
Department of Biological Sciences, and the Marine Research (MA-RE) Institute, University of Cape Town
South Africa

Madhu Verma
Lead author
World Resources Institute
India

Andres Viña
Lead author
Michigan State University
United States of America

Hazel Arceo
Review editor
Marine Science Institute, University of the Philippines
Philippines

Stanley Asah
Review editor
University of Washington
United States of America

Rodolfo Dirzo
Review editor
Stanford University - Woods Institute for the Environment
United States of America

Eric Lambin
Review Editor
Earth & Life Institute, Université catholique de Louvain and Department of Earth System Science, School of Earth, Energy & Environmental Sciences, Stanford University
Belgium/United States of America

Jayalaxshmi Mistry
Review editor
Royal Holloway University of London
United Kingdom of Great Britain and Northern Ireland

Sebsebe Demissew Woodmatas
Review editor
Addis Ababa University
Ethiopia

Pedro Jaureguiberry
Fellow
IMBIV (CONICET-Universidad Nacional de Córdoba)
Argentina

Rashad Salimov
Fellow
Institute of Botany of ANAS
Azerbaijan

Uttam Babu Shrestha
Fellow
University of Southern Queensland,
Australia

Anna Sidorovich
Fellow
Scientific and Practical Centre for Bioresources of National Academy of Sciences of Belarus
Belarus

Chapter 3

Stuart H.M. Butchart
Coordinating lead author
BirdLife International
United Kingdom of Great Britain and Northern Ireland

Suneetha Mazhenchery Subramanian
Coordinating lead author
UNU-Institute for the Advanced Study of Sustainability
India

Patricia Miloslavich de Klein
Coordinating lead author
University of Tasmania/Universidad Simon Bolivar
Australia/Venezuela (Bolivarian Republic of)

Belinda Reyers
Coordinating lead author
Future Africa, University of Pretoria
South Africa

Cristina Adams
Lead author
School of Arts, Sciences and Humanity, University of São Paulo
Brazil

Elena Bennett
Lead author
McGill University
Canada

Bálint Czúcz
Lead author
MTA Centre for Ecological Research, Institute of Ecology and Botany
Hungary

Leonardo Galetto
Lead author
Universidad Nacional de Córdoba, Argentina

Kathleen Galvin
Lead author
Colorado State University
United States of America

Leah Gerber
Lead author
School of Life Sciences, Arizona State University
United States of America

Tamrat Gode
Lead author
Addis Ababa University
Ethiopia

Walter Jetz
Lead author
Imperial College London (P/T) and Yale University
United States of America

Ishmael Bobby Mphangwe Kosamu
Lead author
University of Malawi
Malawi

Maria Gabriela Palomo
Lead author
National History Museum
Argentina

Mostafa Panahi
Lead author
Science and Research Branch, Islamic Azad University
Iran (Islamic Republic of)

Victoria Reyes-García
Lead author
Universitat Autònoma de Barcelona (UAB)
Spain

Elizabeth Selig
Lead author
Stanford University
United States of America

Gopal Shankar Singh
Lead author
Banaras Hindu University
India

David Tarkhnishvili
Lead author
Ilia State University
Georgia

Haigen Xu
Lead author
Nanjing Institute of Environmental Sciences, Ministry of Environmental Protection of China
China

Fikret Berkes
Review editor
University of Manitoba
Canada

Thomas Brooks
Review editor
IUCN (International Union for Conservation of Nature)
Switzerland

Abigail Lynch
Fellow
U.S. Geological Survey, National Climate Adaptation Science Center
United States of America

Tuyeni Heita Mwampamba
Fellow
Institute of Ecosystems & Sustainability Research, National Autonomous University of Mexico
Mexico

Aibek Samakov
Fellow
Universität Tübingen
Kyrgyzstan

Chapter 4

Almut Arneth
Coordinating lead author
Karlsruhe Institute of Technology
Germany

Guy F. Midgley
Coordinating lead author
University of Stellenbosch
South Africa

Rinku Roy Chowdhury
Coordinating lead author
Clark University
United States of America

Yunne-Jai Shin
Coordinating lead author
Institut de recherche pour le développement (IRD)
France

Yaw Agyeman Boafo
Lead author
Centre for Climate Change and Sustainability Studies, University of Ghana
Ghana

ANNEX IV
List of expert reviewers

Expert reviewers of the IPBES global assessment report on biodiversity and ecosystem services

We would like to thank all of the IPBES Multidisciplinary Expert Panel members and the Bureau – both past and current - for submitting comments during the internal and external expert review stages.

All of the following expert reviewers listed below that directly participated in the global assessment as authors submitted comments on chapters to which they were not involved.

We would like to acknowledge the following governments (including the national focal point) for submitting comments on the IPBES global assessment:

- **Government of Argentina**
- **Government of Australia**
- **Government of Armenia**
- **Government of Belgium**
- **Government of Benin**
- **Government of Brazil**
- **Government of Canada**
- **Government of China**
- **Government of Colombia**
- **Government of Ethiopia**
- **Government of Finland**
- **Government of France**
- **Government of Germany**
- **Government of Guinea-Bissau**
- **Government of India**
- **Government of Iran**
- **Government of Japan**
- **Government of Malawi**
- **Government of Mexico**
- **Government of Moldova**
- **Government of the Netherlands**
- **Government of New Zealand**
- **Government of Norway**
- **Government of Peru**
- **Government of Romania**
- **Government of South Africa**
- **Government of St. Lucia**
- **Government of Sweden**
- **Government of Switzerland**
- **Government of Togo**
- **Government of the United Kingdom of Great Britain and Northern Ireland**
- **Government of Uruguay**
- **Government of the United States of America**
- **The European Union**

The Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES)

is the intergovernmental body which assesses the state of biodiversity and ecosystem services, in response to requests from Governments, the private sector and civil society.

The mission of IPBES is to strengthen the science-policy interface for biodiversity and ecosystem services for the conservation and sustainable use of biodiversity, long-term human well-being and sustainable development.

IPBES has a collaborative partnership arrangement with UNEP, UNESCO, FAO and UNDP. Its secretariat is hosted by the German government and located on the UN campus, in Bonn, Germany.

Scientists from all parts of the world contribute to the work of IPBES on a voluntary basis. They are nominated by their government or an organisation, and selected by the Multidisciplinary Expert Panel (MEP) of IPBES. Peer review forms a key component of the work of IPBES to ensure that a range of views is reflected in its work, and that the work is complete to the highest scientific standards.

INTERGOVERNMENTAL SCIENCE-POLICY PLATFORM ON BIODIVERSITY AND ECOSYSTEM SERVICES (IPBES)
